# Preface

Robots are executed on RoboServer through an API (Java or .Net). You may use the API directly in your own application or indirectly when you execute robots using Management Console.

 This guide contains the deprecated APIs that are now referred to as legacy APIs.

This guide consists of three parts:

- *Java Programmer's Guide*, which describes the legacy API used in Java programs.
- *.NET Programmer's Guide*, which describes the legacy API used in .NET applications, including C# programs.

Java and .NET API reference documentation is available in your offline documentation folder. The Java API documentation is also available on the online documentation site. For more information, see the *Kofax RPA Installation Guide*.

## Related Documentation

The documentation set for Kofax RPA is available here:<sup>1</sup>

<https://docshield.kofax.com/Portal/Products/RPA/11.5.0-nlfihq5gwr/RPA.htm>

In addition to this guide, the documentation set includes the following items:

### ***Kofax RPA Release Notes***

Contains late-breaking details and other information that is not available in your other Kofax RPA documentation.

### ***Kofax RPA Technical Specifications***

Contains information on supported operating systems and other system requirements.

### ***Kofax RPA Installation Guide***

Contains instructions on installing Kofax RPA and its components in a development environment.

### ***Kofax RPA Upgrade Guide***

Contains instructions on upgrading Kofax RPA and its components to a newer version.

---

<sup>1</sup> You must be connected to the Internet to access the full documentation set online. For access without an Internet connection, see the *Installation Guide*.

***Kofax RPA Administrator's Guide***

Describes administrative and management tasks in Kofax RPA.

***Kofax RPA Help***

Describes how to use Kofax RPA. The Help is also available in PDF format and known as *Kofax RPA User's Guide*.

***Kofax RPA Best Practices Guide for Robot Lifecycle Management***

Offers recommended methods and techniques to help you optimize performance and ensure success while using Robot Lifecycle Management in your Kofax RPA environment.

***Kofax RPA Getting Started with Robot Building Guide***

Provides a tutorial that walks you through the process of using Kofax RPA to build a robot.

***Kofax RPA Getting Started with Document Transformation Guide***

Provides a tutorial that explains how to use Document Transformation functionality in a Kofax RPA environment, including OCR, extraction, field formatting, and validation.

***Kofax RPA Desktop Automation Service Configuration Guide***

Describes how to configure the Desktop Automation Service required to use Desktop Automation on a remote computer.

***Kofax RPA Integration API documentation***

Contains information about the Kofax RPA Java API and the Kofax RPA .NET API, which provide programmatic access to the Kofax RPA product. The Java API documentation is available from both the online and offline Kofax RPA documentation, while the .NET API documentation is available only offline.

 The Kofax RPA APIs include extensive references to RoboSuite, the original product name. The RoboSuite name is preserved in the APIs to ensure backward compatibility. In the context of the API documentation, the term RoboSuite has the same meaning as Kofax RPA.

## Training

Kofax offers both classroom and computer-based training to help you make the most of your Kofax RPA solution. Visit the Kofax Education Portal at <https://learn.kofax.com/> for details about the available training options and schedules.

Also, you can visit the Kofax Intelligent Automation SmartHub at <https://smarthub.kofax.com/> to explore additional solutions, robots, connectors, and more.

## Getting help with Kofax products

The [Kofax Knowledge Portal](#) repository contains articles that are updated on a regular basis to keep you informed about Kofax products. We encourage you to use the Knowledge Portal to obtain answers to your product questions.

To access the Kofax Knowledge Portal, go to <https://knowledge.kofax.com>.

 The Kofax Knowledge Portal is optimized for use with Google Chrome, Mozilla Firefox, or Microsoft Edge.

The Kofax Knowledge Portal provides:

- Powerful search capabilities to help you quickly locate the information you need.  
Type your search terms or phrase into the **Search** box, and then click the search icon.
- Product information, configuration details and documentation, including release news.  
To locate articles, go to the Knowledge Portal home page and select the applicable Solution Family for your product, or click the View All Products button.

From the Knowledge Portal home page, you can:

- Access the Kofax Community (for all customers).  
On the Resources menu, click the **Community** link.
- Access the Kofax Customer Portal (for eligible customers).  
Go to the [Support Portal Information](#) page and click **Log in to the Customer Portal**.
- Access the Kofax Partner Portal (for eligible partners).  
Go to the [Support Portal Information](#) page and click **Log in to the Partner Portal**.
- Access Kofax support commitments, lifecycle policies, electronic fulfillment details, and self-service tools.  
Go to the [Support Details](#) page and select the appropriate article.

## Chapter 1

# Java Programmer's Guide

This chapter describes how to execute Robots using the Kofax RPA legacy Java API. The guide assumes that you know how to write simple robots, and that you are familiar with the Java programming language.

 The `printStackTrace` method is deprecated in Kofax Kapow version 9.6 and later.

You can find information about specific Java classes in the Application Programming Interface section on the Kofax RPA Product Documentation site: <https://docshield.kofax.com/Portal/Products/RPA/11.5.0-nlfihq5gwr/RPA.htm>. This information is also available in your offline documentation folder. For more details, see the *Kofax RPA Installation Guide*.

## Java Basics

Robots run by the Management Console are executed using the Java API, which allows you to send requests to a `RoboServer` that instructs it to execute a particular robot. This is a classic client/server setup in which Management Console acts as the client and `RoboServer` as the server.

By using the API, any Java based application can become a client to `RoboServer`. In addition to running robots that store data in a database, you can also have the robots return data directly back to the client application. Here are some examples:

- Use multiple robots to do a federated search, which aggregates results from multiple sources in real time.
- Run a robot in response to an event on your application back end. For instance, run a robot when a new user signs up, to create accounts on web-based systems not integrated directly into your back end.

This guide introduces the core classes, and how to use them for executing robots. We will also describe how to provide input to robots, and control their execution on `RoboServer`.

The Java API is a JAR file located in `/API/legacy/robosuite-java-api/lib/robosuite-api.jar` inside the Kofax RPA installation folder. See "Important Folders" in the *Installation Guide* for details. All examples in this guide are also found in `/API/robosuite-java-api/examples`. Located next to the Java API are five additional JAR files which comprise the external dependencies of the API. Most basic API tasks such as executing robots can be done without using any of these third-party libraries, while some advanced features do require the usage of one or more of these libraries. The examples in this guide specify when such libraries are required.

**i** The Java API JAR file requires JAXP version 1.5, so legacy implementations, such as Xalan-Java 2.7.2, will not work with the Java JAR file.

## First Example

The following is the code required to execute the robot named `NewsMagazine.robot`, which is located in the `Tutorials` folder in the default project. The robot writes its results using the `Return Value` step action, which makes it easy to handle the output programmatically using the API. Other robots (typically those run in a schedule by `Management Console`) store their data directly in a database using the `Store in Database` step action, in which case data collected by the robot is not returned to the API client.

In the following example, the `NewsMagazine` robot is executed and the output is processed programmatically.

### Execute a Robot without input:

```
import com.kapowtech.robosuite.api.java.repository.construct.*;
import com.kapowtech.robosuite.api.java.rql.*;
import com.kapowtech.robosuite.api.java.rql.construct.*;

/**
 * Example that shows you how to execute NewsMagazine.robot from tutorial1
 */
public class Tutorial1 {

    public static void main(String[] args) throws ClusterAlreadyDefinedException {

        RoboServer server = new RoboServer("localhost", 50000);
        boolean ssl = false;
        Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, ssl);

        Request.registerCluster(cluster); // you can only register a cluster once per
        application

        try {
            Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
            request.setRobotLibrary(new DefaultRobotLibrary());
            RQLResult result = request.execute("MyCluster");

            for (Object o : result.getOutputObjectsByName("Post")) {
                RQLObject value = (RQLObject) o;
                String title = (String) value.get("title");
                String preview = (String) value.get("preview");
                System.out.println(title + ", " + preview);
            }
        }
    }
}
```

The following table lists the classes involved and their responsibilities.

RoboServer	This is a simple value object that identifies a RoboServer that can execute robots. Each RoboServer must be activated by a Management Console and assigned KCU before use.
Cluster	A cluster is a group of RoboServers functioning as a single logical unit.

Request	This class is used to construct the robot request. Before you can execute any requests, you must register a cluster with the Request class.
DefaultRobotLibrary	A robot library instructs RoboServer on where to find the robot identified in the request. Later examples explore the various robot library types and when/how to use them.
RQLResult	This class contains the result of a robot execution. The result contains value responses, with log and server messages.
RQLObject	Each value that is returned from a robot using the Return Value action can be accessed as an RQLObject.

The following line tells the API that our RoboServer is running on localhost port 50000.

```
RoboServer server = new RoboServer("localhost", 50000);
```

The following code defines a cluster with a single RoboServer. The cluster is registered with the Request class, giving you the ability to execute requests on this cluster. Each cluster can only be registered once.

#### Registering a cluster:

```
boolean ssl = false;
Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, ssl);
Request.registerCluster(cluster);
```

The following code creates a request that executes the robot named `NewsMagazine.robot` located at `Library:/Tutorials.Library:/` referring to the robot `Library` configured for the request. Here the `DefaultRobotLibrary` is used, which instructs `RoboServer` to look for the robot in the local file system for the server. See [Robot Libraries](#) for more information on how to use robot libraries.

```
Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
request.setRobotLibrary(new DefaultRobotLibrary());
```

The next line executes the robot on the cluster named `MyCluster` (the cluster previously registered) and returns the result once the robot is done. By default, `execute` throws an exception if the robot generates an API exception.

```
RQLResult result = request.execute("MyCluster")
```

Here we process the extracted values. First, we get all extracted values of the type named `Post` and iterate through them. For each `RQLObject`, we access the attributes of the `Post` type and print the result. Attributes and mappings are discussed in a later section.

```
for (Object o : result.getOutputObjectsByName("Post")) {
    RQLObject value = (RQLObject) o;
    String title = (String) value.get("title");
    String preview = (String) value.get("preview");
    System.out.println(title + ": " + preview);
}
```

## Robot Input

Most robots executed through the API are parameterized through input, such as a search keyword or login credentials. Input to a robot is part of the request to `RoboServer` and is provided using the `createInputVariable` method on the request.

**Input using implicit RQObjectBuilder:**

```
Request request = new Request("Library:/Input.robot");
request.createInputVariable("userLogin").setAttribute("username", "scott")
    .setAttribute("password", "tiger");
```

In this example, a `Request` is created and `createInputVariable` is used to create an input variable named `userLogin`. Then, `setAttribute` is used to configure the user name and password attributes of the input variable.

The preceding example is a common shorthand notation, but can also be expressed in more detail by using the `RQObjectBuilder`:

**Input using explicit RQObjectBuilder:**

```
Request request = new Request("Library:/Input.robot");
RQObjectBuilder userLogin = request.createInputVariable("userLogin");
userLogin.setAttribute("username", "scott");
userLogin.setAttribute("password", "tiger");
```

The two examples are identical. The first utilizes the cascading method invocation on the anonymous `RQObjectBuilder` and therefore shorter.

When `RoboServer` receives this request, the following occurs:

- `RoboServer` loads `Input.robot` (from whatever `RobotLibrary` is configured for the request).
- `RoboServer` verifies that the robot has a variable named `userLogin` and that this variable is marked as input.
- `RoboServer` now verifies that the attributes configured using `setAttribute` are compatible with the type of variable `userLogin`. As a result, the type must have attributes named `username` and `password` and must both be text-based attributes (the next section describes the mapping between the API and Design Studio attributes).
- If all input variables are compatible, `RoboServer` starts executing the robot.

If a robot requires multiple input variables, you must create all of them to execute the robot. You only have to configure required attributes; any no-required attributes that you do not configure through the API will have a null value. If you have a robot that requires a login to both Facebook and Twitter, you could define the input like this.

```
Request request = new Request("Library:/Input.robot");
request.createInputVariable("facebook").setAttribute("username", "scott")
    .setAttribute("password", "facebook123");
request.createInputVariable("twitter").setAttribute("username", "scott")
    .setAttribute("password", "twitter123");
```

## Attribute Types

When you define a new type in Design Studio, select a type for each attribute. Some attributes can contain text, like Short text, Long Text, Password, HTML, XML, and when used inside a robot, there may be requirements to store text in these attributes. If you store text in an XML attribute, the text must be a valid XML document. This validation occurs when the type is used inside a robot, but as the API does not know anything about the type, it does not validate attribute values in the same manner. As a result, the API only has eight attribute types and Design Studio has 19 available types. This table shows the mapping between the API and Design Studio attribute types.

## API to Design Studio mapping

API Attribute Type	Design Studio Attribute Type
Text	Short Text, Long Text, Password, HTML, XML, Properties, Language, Country, Currency, Refind Key
Integer	Integer
Boolean	Boolean
Number	Number
Character	Character
Date	Date
Session	Session
Binary	Binary, Image, PDF

The API attribute types are then mapped to Java in the following way.

## Java Types for Attributes

API Attribute Type	Java Class
Text	<code>java.lang.String</code>
Integer	<code>java.lang.Long</code>
Boolean	<code>java.lang.Boolean</code>
Number	<code>java.lang.Double</code>
Character	<code>java.lang.Character</code>
Date	<code>java.util.Date</code>
Session	<code>com.kapowtech.robosuite.api.construct.Session</code>
Binary	<code>com.kapowtech.robosuite.api.construct.Binary</code>

The `setAttribute` method of `RQLObjectBuilder` is overloaded so you do not need to specify the attribute type explicitly when configuring an attribute through the API, as long as the right Java class is used as an argument. Here is an example that shows how to set the attributes for an object with all possible Design Studio attribute types.

### Recommended usage of `setAttribute`:

```
Request request = new Request("Library:/AllTypes.robot");
RQLObjectBuilder inputBuilder = request.createInputVariable("AllTypes");
inputBuilder.setAttribute("anInt", new Long(42L));
inputBuilder.setAttribute("aNumber", new Double(12.34));
inputBuilder.setAttribute("aBoolean", Boolean.TRUE);
inputBuilder.setAttribute("aCharacter", 'c');
inputBuilder.setAttribute("aShortText", "some text");
inputBuilder.setAttribute("aLongText", "a longer test");
inputBuilder.setAttribute("aPassword", "secret");
inputBuilder.setAttribute("aHTML", "<html>text</html>");
inputBuilder.setAttribute("anXML", "<tag>text</tag>");
inputBuilder.setAttribute("aDate", new Date());
inputBuilder.setAttribute("aBinary", new Binary("some bytes".getBytes()));
```

```
inputBuilder.setAttribute("aPDF", (Binary) null);
inputBuilder.setAttribute("anImage", (Binary) null);
inputBuilder.setAttribute("aProperties", "name=value\nname2=value2");
inputBuilder.setAttribute("aSession", (Session) null);
inputBuilder.setAttribute("aCurrency", "USD");
inputBuilder.setAttribute("aCountry", "US");
inputBuilder.setAttribute("aLanguage", "en");
inputBuilder.setAttribute("aRefindKey", "Never use this a input");
```

The preceding example explicitly uses `new Long(42L)` and `new Double(12.34)`, although `42L` and `12.34` would be sufficient due to auto-boxing. Also notice that we have to cast null values, because the Java compiler cannot otherwise determine which of the overloaded `setAttribute` methods to call. However, as unconfigured attributes will automatically be null, you never need to set null explicitly.

It is possible to specify the `Attribute` and `AttributeType` explicitly when creating input using the API. This approach is not recommended, but may be needed in rare cases and would look similar to the following.

#### Incorrect usage of `setAttribute`:

```
Request request = new Request("Library:/AllTypes.robot");
RQLObjectBuilder inputBuilder = request.createInputVariable("AllTypes");
inputBuilder.setAttribute(new Attribute("anInt", "42", AttributeType.INTEGER));
inputBuilder.setAttribute(new Attribute("aNumber", "12.34", AttributeType.NUMBER));
inputBuilder.setAttribute(new Attribute("aBoolean", "true", AttributeType.BOOLEAN));
inputBuilder.setAttribute(new Attribute("aCharacter", "c", AttributeType.CHARACTER));
inputBuilder.setAttribute(new Attribute("aShortText", "some text",
AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aLongText", "a longer test",
AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aPassword", "secret", AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aHTML", "<html>bla</html>",
AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("anXML", "<tag>text</tag>",
AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aDate", "2012-01-15 23:59:59.123",
AttributeType.DATE));
inputBuilder.setAttribute(new Attribute("aBinary",
Base64Encoder.encode("some bytes".getBytes()), AttributeType.BINARY));
inputBuilder.setAttribute(new Attribute("aPDF", null, AttributeType.BINARY));
inputBuilder.setAttribute(new Attribute("anImage", null, AttributeType.BINARY));
inputBuilder.setAttribute(new Attribute("aProperties", "name=value\nname2=value2",
AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aSession", null, AttributeType.SESSION));
inputBuilder.setAttribute(new Attribute("aCurrency", "USD", AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aCountry", "US", AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aLanguage", "en", AttributeType.TEXT));
inputBuilder.setAttribute(new Attribute("aRefindKey", "Never use this a input",
AttributeType.TEXT));
```

All attribute values must be provided in the form of strings. The string values are then converted to the appropriate Java objects based on the attribute type provided. This is only useful if you build other generic APIs on top of the Kofax RPA Java API.

## Execution Parameters

In addition to the `createInputVariable` method, the `Request` contains a number of methods that control how the robot executes on `RoboServer`.

**Execution Control Methods on Request**

<code>setMaxExecutionTime(int seconds)</code>	Controls the execution time of the robot. When this time has elapsed, the robot is stopped by RoboServer. The timer does not start until the robot begins to execute, so if the robot is queued on RoboServer, this is not taken into account.
<code>setStopOnConnectionLost(boolean)</code>	When true (default), the robot stops if RoboServer discovers that the connection to the client application has been lost. You should have a very good reason for setting this value to false; if your code is not written to handle this value, your application will not perform as expected.
<code>setStopRobotOnApiException(boolean)</code>	When true (default), the robot is stopped by RoboServer after the first API exception is raised. By default, most steps in a robot raise an API exception if the step fails to execute. Configure this value on the Error Handling tab for the step. When set to false, the robot continues to execute regardless of API exceptions. However, unless your application is using the <code>RequestExecutor</code> streaming execution mode, an exception is still thrown by <code>execute()</code> . Be cautious when setting it to false.
<code>setUsername(String), setPassword(String)</code>	Sets the RoboServer credentials. RoboServer can be configured to require authentication. When this option is enabled, the client must provide credentials or RoboServer rejects the request.
<code>setRobotLibrary(RobotLibrary)</code>	A robot library instructs RoboServer on where to find the robot identified in the request. For more examples related to the various library types and their usage, see <a href="#">Robot Libraries</a> .
<code>setExecutionId(String)</code>	Allows you to set the <code>executionId</code> for this request. If you do not provide one, RoboServer generates one automatically. The execution ID is used for logging and is also needed to stop the robot programmatically. The ID must be globally unique (over time). If two robots use the same execution ID, the logs will be inconsistent.
<code>setProject(String)</code>	This method is used solely for logging purposes. Management Console uses this field to link log messages to project, so the log views can filter by project. If your application is not using the <code>RepositoryRobotLibrary</code> , you should probably set this value to inform the RoboServer logging system which project (if any) this robot belongs to.

## Robot Libraries

In Design Studio, robots are grouped into projects. If you look in the file system, you can see that these projects are identified by a folder named Library (see the "Libraries and Robot Projects" topic in *Help for Kofax RPA* for details).

When you build the execute request for `RoboServer`, you identify the robot by a robot URL:

```
Request request = new Request("Library:/Input.robot");
```

Here, `Library:/` is a symbolic reference to a robot library, in which `RoboServer` should look for the robot. The `RobotLibrary` is specified on the builder:

```
request.setRobotLibrary(new DefaultRobotLibrary());
```

Three different robot library implementations are available, and your selection depends on the deployment environment.

### Robot Libraries

Library Type	Description
<code>DefaultRobotLibrary</code>	<p>This library configures <code>RoboServer</code> to look for the robot in the current project folder, which is defined in the Settings application.</p> <p>If you have multiple <code>RoboServers</code>, you must deploy your robots on all <code>RoboServers</code>.</p> <p>This robot library is not cached, so the robot is reloaded from disk with every execution. This approach makes the library usable in a development environment where robots change often, but it is not suitable for a production environment.</p>

Library Type	Description
EmbeddedFileBasedRobotLibrary	<p>This library is embedded in the execute request sent to RoboServer. To create this library you must create a zip file containing the robots and all dependencies (types, snippets, and resources). Use the <b>Tools &gt; Create Robot Library File</b> menu in Design Studio.</p> <p>The library is sent with every request, which adds some overhead for large libraries, but the libraries are cached on RoboServer, which offers best possible performance.</p> <p>One strength is that robots and code can be deployed as a single unit, which offers clean migration from a QA environment to production environment. However, if the robots change often, you have to redeploy them often.</p> <p>You can use the following code to configure the embedded robot library for your request.</p> <pre>Request request = new Request("Library:/Tutorials/ NewsMagazine.robot"); RobotLibrary library = new EmbeddedFileBasedRobotLibrary (new FileInputStream ("c:\\embeddedLibrary.robotlib")); request.setRobotLibrary(library);</pre>

Library Type	Description
RepositoryRobotLibrary	<p>This is the most flexible robot library.</p> <p>This library uses the Management Consoles built-in repository as a robot library. When you use this library, RoboServer contacts the Management Console, which sends a robot library containing the robot and its dependencies.</p> <p>Caching occurs on a per robot basis, inside both Management Console and RoboServer. Inside Management Console, the generated library is cached based on the robot and its dependencies. On RoboServer, the cache is based on a timeout, so it does not have to ask the Management Console for each request. In addition, the library loading between RoboServer and Management Console uses HTTP public/private caching, to further reduce bandwidth.</p> <p>If <code>NewsMagazine.robot</code> is uploaded to the Management Console, you can use the repository robot library when executing the robot:</p> <pre data-bbox="799 892 1458 1094">Request request = new Request("Library:/Tutorials/ NewsMagazine.robot"); RobotLibrary library = new RepositoryRobotLibrary("http:// localhost:50080", "Default Project", 60000); request.setRobotLibrary(library);</pre> <p>This command instructs RoboServer to load the robot from a local Management Console and caches it for one minute before checking with the Management Console to see if a new version of the robot (its type and snippets) is changed.</p> <p>In addition, any resource loaded through the <code>Library:/</code> protocol causes the RoboServer to request the resource directly from the Management Console.</p>

## Java Advanced

This section describes advanced API features, including output streaming, logging and SSL configuration, as well as parallel execution.

### Load Distribution and Failover

Inside the `RequestExecutor`, the executor is given an array of `RoboServers`. As the executor is constructed, it tries to connect to each `RoboServer`. Once connected, it sends a ping request to each `RoboServer` to discover how the server is configured.

#### Load balanced executor:

```
RoboServer prod = new RoboServer("prod.kapow.local", 50000);
RoboServer prod2 = new RoboServer("prod2.kapow.local", 50000);
Cluster cluster = new Cluster("Prod", new RoboServer[]{ prod, prod2}, false);
```

```
Request.registerCluster(cluster);
```

The load is distributed to each online RoboServer in the cluster, based on the number of unused execution slots on the RoboServer. The next request is always distributed to the RoboServer with the most available slots. The number of available execution slots is obtained through the initial ping response, and the executor keeps track of each robot it starts and when it completes. The number of execution slots on a RoboServer is determined by the **Max concurrent robots** setting in the Management Console > Admin > RoboServers section.

If a RoboServer goes offline, it does not receive any robot execution requests before it has successfully responded to the ping request.

## One Client Rule

By default, API connections are limited to 20 connections. However, to ensure the best performance, we recommend that you have only one API client using a given cluster of RoboServers. If you have too many JVMs running robots against the same RoboServers, it will result in reduced performance.

Although the following is not recommended, if your environment requires the handling of a higher volume, you can configure the connection limit by adjusting the `kapow.max.multiplexing.clients` system property in the `common.conf` file.

## Executor Logger

When you execute a request, the `execute` method throws an exception if a robot generates an error. Other types of errors and warnings are reported through the `ExecutorLogger` interface. In the previous examples, `ExecutionLogger` was not provided when executing robots, which is the default implementation that writes to `System.out`.

The following is an example of how the `ExecutorLogger` reports if one of the RoboServers goes offline. In this example, a cluster is configured with a RoboServer that is not online.

### ExecutorLogger, offline server example:

```
RoboServer rs = new RoboServer("localhost", 50000);
Cluster cluster = new Cluster("name", new RoboServer[]{rs}, false);
Request.registerCluster(cluster);
```

If you run this example, it writes the following to the console.

### ExecutorLogger, offline RoboServer console output:

```
RoboServer{host='localhost', port=50000} went offline.
Connection refused
```

If you do not need your application to write directly to `System.out`, you can provide a different `ExecutorLogger` implementation, when registering the cluster.

### Use DebugExecutorLogger:

```
Request.registerCluster(cluster, new DebugExecutorLogger());
```

This example uses the `DebugExecutorLogger()`, which also writes to `System.out`, but only if the API debugging is enabled. You can provide your own implementation of the `ExecutorLogger`,

to control how error messages are handled. Check the `ExecutorLogger` JavaDoc for additional details.

## Data Streaming

If you need to present the results from a robot execution in real-time, you can use the API to return the extracted values immediately instead of waiting for the robot to finish its execution and access the `RQLResult`.

The API offers the possibility to receive a callback every time the API receives a value that was returned by the robot. Do this through the `RobotResponseHandler` interface.

### Response streaming using `AbstractFailFastRobotResponseHandler`:

```
public class DataStreaming {

    public static void main(String[] args) throws ClusterAlreadyDefinedException {

        RoboServer server = new RoboServer("localhost", 50000);
        Cluster cluster = new Cluster("MyCluster", new RoboServer[] {server}, false);
        Request.registerCluster(cluster);

        try {
            Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
            RobotResponseHandler handler = new AbstractFailFastRobotResponseHandler()
            {
                public void handleReturnedValue(RobotOutputObjectResponse response,
                Stoppable stoppable) throws RQLException {
                    RQLObject value = response.getOutputObject();
                    Long personId = (Long) value.get("personId");
                    String name = (String) value.get("name");
                    Long age = (Long) value.get("age");
                    System.out.println(personId + ", " + name + ", " + age);
                }
            };
            request.execute("MyCluster", handler);
        }
    }
}
```

The preceding example uses the second `execute` method of the request, which expects a `RobotResponseHandler` in addition to the name of the cluster to execute the robot on. In this example, create a `RobotResponseHandler` by extending `AbstractFailFastRobotResponseHandler`, which provides default error handling, to handle only the values returned by the robot.

The `handleReturnedValue` method is called whenever the API receives a returned value from `RoboServer`. The `AbstractFailFastRobotResponseHandler` used in this example throws exceptions in the same way as the non-streaming `execute` method. This means that an exception is thrown in response to any API exceptions generated by the robot.

The `RobotResponseHandler` has several methods that can be grouped into three categories.

### Robot life cycle events

Methods called when the robot execution state changes on `RoboServer`, such as when it starts and finishes execution.

**Robot data events**

Methods called when the robot returns data or errors to the API.

**Additional error handling**

Methods called due to an error inside RoboServer or in the API.

**RobotResponseHandler - robot life cycle events**

Method name	Description
<code>void requestSent (RoboServer roboServer, ExecuteRequest request)</code>	Called when the <code>RequestExecutor</code> finds the server that executes the request.
<code>void requestAccepted (String executionId)</code>	Called when the found <code>RoboServer</code> accepts the request and puts it into its queue.
<code>void robotStarted (Stoppable stoppable)</code>	Called when the <code>RoboServer</code> begins to execute the robot. This usually occurs immediately after the robot is queued, unless the <code>RoboServer</code> is under a heavy load, or used by multiple API clients.
<code>void robotDone (RobotDoneEvent reason)</code>	Called when the robot is done executing on <code>RoboServer</code> . The <code>RobotDoneEvent</code> is used to specify if the execution terminated normally, due to an error, or if it was stopped.

**RobotResponseHandler - robot data events**

Method name	Description
<code>void handleReturnedValue (RobotOutputObjectResponse response, Stoppable stoppable)</code>	Called when the robot is executed a Return Value action and the value is returned via the socket to the API.
<code>void handleRobotError (RobotErrorResponse response, Stoppable stoppable)</code>	Called when the robot raises an API exception. Under normal circumstances the robot stops executing after the first API exception. This behavior can be overridden by using <code>Request.setStopRobotOnApiException (false)</code> , in which case this method is called multiple times. This approach is useful if you want a data streaming robot to continue to execute regardless of any generated errors.
<code>void handleWriteLog (RobotMessageResponse response, Stoppable stoppable)</code>	Called when the robot executes the Write Log step. This is useful to provide additional logging info from a robot.

**RobotResponseHandler - additional error handling**

Method name	Description
<code>void handleServerError(ServerErrorResponse response, Stoppable stoppable)</code>	Called if RoboServer generates an error. For example, it can happen if the server is too busy to process any requests, or if an error occurs inside RoboServer, which prevents it from starting the robot.
<code>handleError(RQLException e, Stoppable stoppable)</code>	Called if an error occurs inside the API, or most commonly, if the client loses the connection to RoboServer.

Many of the methods include a `Stoppable` object, which can be used to stop in response to a specific error or value returned.

Some methods allow you to throw an `RQLException`, which may have consequences. The thread that calls the handler is the thread that calls `Request.execute()` and exceptions thrown can overload the call stack. If you throw an exception in response to `handleReturnedValue`, `handleRobotError` or `handleWriteLog`, it is your responsibility to invoke `Stoppable.stop()`, or the robot may continue to execute even though the call to `Request.execute()` is completed.

Data streaming is most often used in one of the following use cases.

- Ajax based web applications, where results are presented to the user in real-time. If data is not streamed, results cannot be shown until the robot is done running.
- Robots that return so much data that the client would not be able to hold it all in memory throughout the robot execution.
- Processes that need to be optimized so the extracted values are processed in parallel with the robot execution.
- Processes that store data in databases in a custom format.
- Robots that should ignore or require custom handling of API exceptions (see the following example).

**Response and error collecting using AbstractFailFastRobotResponseHandler:**

```
public class DataStreamingCollectErrorsAndValues {

    public static void main(String[] args) throws ClusterAlreadyDefinedException {

        RoboServer server = new RoboServer("localhost", 50000);
        Cluster cluster = new Cluster("MyCluster", new RoboServer[] {server}, false);
        Request.registerCluster(cluster);

        try {
            Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
            request.setStopRobotOnApiException(false); // IMPORTANT!!
            request.setRobotLibrary(new DefaultRobotLibrary());
            ErrorCollectingRobotResponseHandler handler =
                new ErrorCollectingRobotResponseHandler();
            request.execute("MyCluster", handler);

            System.out.println("Extracted values:");
            for (RobotOutputObjectResponse response : handler.getOutput()) {
                RQLObject value = response.getOutputObject();
                Long personId = (Long) value.get("personId");
                String name = (String) value.get("name");
                Long age = (Long) value.get("age");
            }
        }
    }
}
```

```
        System.out.println(personId + ", " + name + ", " + age);
    }

    System.out.println("Errors:");
    for (RobotErrorResponse error : handler.getErrors()) {
        System.out.println(error.getErrorLocationCode() + ", " +
            error.getErrorMessage());
    }
}

private static class ErrorCollectingRobotResponseHandler extends
    AbstractFailFastRobotResponseHandler {

    private List<RobotErrorResponse> _errors =
        new LinkedList<RobotErrorResponse>();
    private List<RobotOutputObjectResponse> _output =
        new LinkedList<RobotOutputObjectResponse>();
    public void handleReturnedValue
        (RobotOutputObjectResponse response, Stoppable stoppable)
        throws RQLException {
        _output.add(response);
    }

    @Override
    public void handleRobotError(RobotErrorResponse response,
        Stoppable stoppable) throws RQLException {
        // do not call super as this will stop the robot
        _errors.add(response);
    }

    public List<RobotErrorResponse> getErrors() {
        return _errors;
    }

    public List<RobotOutputObjectResponse> getOutput() {
        return _output;
    }
}
```

The preceding example shows how to use a `RobotResponseHandler` that collects returned values and errors. This type of handler is useful if the robot should continue to execute even when errors are encountered, which can be useful if the website is unstable and occasionally times out. Notice that only robot errors (API exceptions) are collected by the handler. If the connection to `RoboServer` is lost, `Request.execute()` still throws an `RQLException`, and the robot is stopped by `RoboServer`.

For more details, check the `RobotResponseHandler` [JavaDoc](#).

## SSL

The API communicates with `RoboServer` through an `RQLService`, which is a `RoboServer` component that listens for API requests on a specific network port. When you start a `RoboServer`, you specify if it should use the encrypted SSL service, or the plain socket service, or both (using two different ports). All `RoboServers` in a cluster must be running the same `RQLService` (although the port may be different).

Assuming we have started a `RoboServer` with the SSL `RQLService` on port 50043:

```
RoboServer -service ssl:50043
```

The following code can be used.

### SSL configuration

```
RoboServer server = new RoboServer("localhost", 50043);
boolean ssl = true;
Cluster cluster = new Cluster("MyCluster", new RoboServer[] {server}, ssl);
Request.registerCluster(cluster);
```

You need to create the cluster as an SSL cluster and specify the SSL port used by each RoboServer. Now all communication between RoboServer and the API will be encrypted.

For this example to work, you need `not-yet-commons-ssl-0.3.17.jar` in your application classpath. You can find it next to the API .jar file inside your Kofax RPA installation.

In addition to data encryption, SSL offers the possibility to verify the identity of the remote party. This type of verification is very important on the Internet. Most often your API client and RoboServers are on the same local network, so you rarely need to verify the identity of the other party, but the API supports this feature should it become necessary.

Because identity verification is almost never used, it is not described in this guide. If you are interested, see the SSL examples included with the Java API.

## Parallel Execution

Both execute methods of the Request are blocking, which means that a thread is required for each robot execution. The examples from the previous sections illustrated direct execution of the robot on the main thread, which is typically not preferable as you can only execute a single robot at a time in a sequential manner.

The following example executes two tutorial robots in parallel. This example uses the `java.util.concurrent` library for multithreading.

### Multithreading Example

```
import com.kapowtech.robosuite.api.java.repository.construct.*;
import com.kapowtech.robosuite.api.java.rql.*;
import com.kapowtech.robosuite.api.java.rql.construct.*;
import com.kapowtech.robosuite.api.java.rql.engine.hotstandby.*;

import java.util.concurrent.*;

public class ParallelExecution {

    public static void main(String[] args) throws Exception {

        RoboServer server = new RoboServer("localhost", 50000);
        Cluster cluster = new Cluster("MyCluster", new RoboServer[] {server},
            false);
        Request.registerCluster(cluster);

        int numRobots = 4;
        int numThreads = 2;
        ThreadPoolExecutor threadPool = new ThreadPoolExecutor(numThreads,
            numThreads, 10, TimeUnit.SECONDS, new LinkedBlockingQueue());
        for (int i = 0; i < numRobots; i++) {
            Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
```

```

        request.setRobotLibrary(new DefaultRobotLibrary());
        threadPool.execute(new RobotRunnable(request));
    }
    threadPool.shutdown();
    threadPool.awaitTermination(60, TimeUnit.SECONDS);
}

// -----
// Inner classes
// -----
static class RobotRunnable implements Runnable {

    Request _request;

    RobotRunnable(Request request) {
        _request = request;
    }

    public void run() {

        try {
            RQLResult result = _request.execute("MyCluster");
            System.out.println(result);
        }
    }
}
}

```

The preceding example creates a `ThreadPoolExecutor` with two threads, and we then create four `RobotRunnables` and execute them on the thread pool. As the thread pool has two threads, two robots start to execute immediately. The remaining two robots are parked in the `LinkedBlockingQueue` and executed in order after the two first robot finish their execution and the thread pool threads become available.

Note that the request is mutable, and to avoid raising conditions, the request is cloned inside the execute method. Because a request is mutable, you should never modify the same request on separate threads.

## Repository Integration

In the Management Console you also specify clusters of `RoboServers`, which are used to execute scheduled robots, as well as robots executed as REST services. The API allows you to use the `RepositoryClient` to obtain cluster information from Management Console. See the `RepositoryClient` documentation for details.

### Repository Integration:

```

public class RepositoryIntegration {
    public static void main(String[] args) throws Exception {

        RepositoryClient client = RepositoryClientFactory.createRepositoryClient
            ("http://localhost:50080", null, null);
        Request.registerCluster(client, "Cluster 1");

        Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
        request.setRobotLibrary(new DefaultRobotLibrary());
        RQLResult result = request.execute("MyCluster");
        System.out.println(result);
    }
}

```

The preceding example shows how to create a `RepositoryClient` that connects to a Management Console deployed on localhost. For this example to work, you must have `commons-logging-1.1.1.jar`, `commons-codec-1.4.jar`, and `commons-httpclient-4.1.jar` included in your classpath.

Authentication is not enabled so null is passed for both user name and password. When you register the `RepositoryClient`, you specify the name of a cluster that exists on the Management Console. It then queries the Management Console to get a list of `RoboServers` configured for this cluster, and check every two minutes to see if the cluster configuration is updated on the Management Console.

This integration allows you to create a cluster on Management Console that you can change dynamically using the Management Console user interface. When you use a Management Console cluster with the API, usage should be exclusive, and you should not use it for scheduling robots, because this would break the One Client rule.

## Under the Hood

This section explains what is happening under the hood when you register a cluster and execute requests.

When you register a cluster with the request, a `RequestExecutor` is created behind the scene. This `RequestExecutor` is stored in a `Map` using the cluster name as key. When a request is executed, the provided cluster name is used to find the associated `RequestExecutor` and execute the request.

### Normal execution

```
public static void main(String[] args) throws InterruptedException,
    SQLException {
    RoboServer server = new RoboServer("localhost", 50000);
    Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, false);
    Request.registerCluster(cluster);
    Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
    request.setRobotLibrary(new DefaultRobotLibrary());
    QLResult result = request.execute("MyCluster");
    System.out.println(result);
}
```

Now write the same example using the `hiddenRequestExecutor` directly.

### Under the hood execution:

```
public static void main(String[] args) throws InterruptedException,
    SQLException {
    RoboServer server = new RoboServer("localhost", 50000);
    Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, false);
    RequestExecutor executor = new RequestExecutor(cluster);

    Request request = new Request("Library:/Tutorials/NewsMagazine.robot");
    request.setRobotLibrary(new DefaultRobotLibrary());
    QLResult result = executor.execute(request);
    System.out.println(result);
}
```

```
}
```

The `RequestExecutor` is hidden by default, so you do not have to keep track of it. You may only create one `RequestExecutor` per cluster, so if you use it directly you need to store a reference to it throughout your application. Using `Request.registerCluster(cluster)` means that you can ignore the `RequestExecutor` and lifecycle rules.

The `RequestExecutor` contains the necessary state and logic, which provides the load balancing and failover features. Using the `RequestExecutor` directly also offers a few extra features.

## RequestExecutor Features

When the `RequestExecutor` is not connected to a repository, you can dynamically add or remove `RoboServers` by calling `addRoboServer(..)` and `removeRoboServer(..)`. These methods modify the distribution list used inside the `RequestExecutor`.

`RequestExecutor.getTotalAvailableSlots()` returns the number of unused execution slots across all `RoboServers` in the internal distribution list.

By using these methods, you can dynamically add `RoboServers` to your `RequestExecutor` once the number of available execution slots becomes low.

When you create the `RequestExecutor`, you may optionally provide an `RQLEngineFactory`. The `RQLEngineFactory` allows you to customize which `RQLProtocol` is used when connecting to a `RoboServer`. This is needed only under rare circumstances, such as to use a client certificate to increase security. See the Certificates chapter in the *Kofax RPA Administrator's Guide* for details.

## Web Applications

The `RequestExecutor` contains a number of internal threads used for sending and receiving requests to `RoboServers`, as well as pinging each known `RoboServer` at regular intervals. These threads are all marked as daemon, which means that they do not prevent the JVM from stopping when the main thread exists. See Thread JavaDoc for details on daemon threads.

If you use the `RequestExecutor` inside a web application, the JVM has a longer life span than your web application, and you can deploy and undeploy your web application while the web container is running. This means that a web application is responsible for stopping any threads that it has created. If the web application does not stop a thread, a memory leak is created when you undeploy the web application. The memory leak occurs because any objects referenced by running threads cannot be garbage collected until the threads stop.

If you use the `RequestExecutor` inside a web application, your code is responsible for shutting down these internal threads, this is done by calling `Request.shutdown()` or `RequestExecutor.shutdown()` if your code created the `RequestExecutor` explicitly.

This example shows how to use a `ServletContextListener` to shut down the API correctly when a web application is undeployed. You must define the context listener in your application `web.xml`.

### Proper shutdown in web application:

```
import com.kapowtech.robosuite.api.java.repository.construct.*;
import com.kapowtech.robosuite.api.java.rql.*;
import com.kapowtech.robosuite.api.java.rql.construct.*;
```

```
import javax.servlet.*;

public class APIShutdownListener implements ServletContextListener {
    public void contextInitialized(ServletContextEvent servletContextEvent) {
        RoboServer server = new RoboServer("localhost", 50000);
        Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server},
            false);
        try {
            Request.registerCluster(cluster);
        }
        catch (ClusterAlreadyDefinedException e) {
            throw new RuntimeException(e);
        }
    }

    public void contextDestroyed(ServletContextEvent servletContextEvent) {
        Request.shutdown();
    }
}
```

`contextDestroyed` is called when the web container undeploys the application.

`Request.shutdown()` is called to ensure that all internal threads in the hidden `RequestExecutor` are stopped correctly.

As `contextInitialized` cannot throw any unchecked exceptions, you have to wrap the `ClusterAlreadyDefinedException` in a `RunTimeException`. Due to the class loader hierarchy in Java web containers, it is possible to get this exception if the application is deployed twice. It only occurs if the API .jar file was loaded by a common class loader and not by the individual application class loader.

## API Debugging

The API can provide additional information for debugging purposes. To enable API debugging, you need to configure the system property `DEBUG_ON`. The value of this property must be a package/class name in the API.

For example, if you are interested in the data transmissions between the API and `RoboServer`, you could ask for debugging information for package `com.kapowtech.robosuite.api.java.rql.io`. While you are developing, do this by directly setting the system property in code:

### Enabling Debug:

```
System.setProperty("DEBUG_ON", "com.kapowtech.robosuite.api.java.rql.io");
RoboServer server = new RoboServer("localhost", 50000);
Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, false);
Request.registerCluster(cluster);
```

If you are debugging an application in production, you can define the system property through the command line.

### Enabling Debug:

```
java -DDEBUG_ON=com.kapowtech.robosuite.api.java.rql.io
```

If you are interested in debugging from multiple packages, separate the package names by commas. Instead of a package name, you can provide the argument `ALL`, to have debugging from all packages printed.

## Repository API

The Repository API allows you to query the repository of Management Console to get a list of projects, robots, and the input required to call a robot. It also allows you to programmatically deploy robots, types, and resource files.

### Dependencies

To use the Repository API, add all `.jar` files from the `API/robosuite-java-api/lib` folder located in the Kofax RPA installation folder to the `classpath` of your project.

Use Java 8 or later.

### Repository Client

Communication with the repository is achieved through the `RepositoryClient` in the `com.kapowtech.robosuite.api.java.repository.engine`.

#### Create RepositoryClient:

```
public static void main(String[] args) {  
    String username = "admin";  
    String password = "admin";  
    try  
    {  
        RepositoryClient client = RepositoryClientFactory.  
            createRepositoryClient("http://localhost:50080/",  
                username, password);  
        Project[] projects = client.getProjects();  
        for (Project project : projects) {  
            System.out.println(project.getName());  
        }  
    }  
    catch(  
        RepositoryClientException e)  
    {  
        e.printStackTrace();  
    }  
}
```

Here, a `RepositoryClient` is configured to connect to the repository of Management Console on `http://localhost:50080/`, with a user name and password.

Once the `RepositoryClient` is created, the `getProjects()` method is used to query the repository for a list of projects. Notice that when calling any of the `RepositoryClient` methods, a `RepositoryClientException` is thrown if an error occurs.

The `RepositoryClient` has the following methods.

**Methods of the RepositoryClient:**

Method signature	Description
<code>void deleteResource(String projectName, String resourceName, boolean silent)</code>	Deletes a resource from a project. If <code>silent</code> is true, no error is generated if the resource does not exist. The <code>resourceName</code> argument uses the full path of the resource.
<code>void deleteRobot(String projectName, String robotName, boolean silent)</code>	Deletes a robot from a project. The <code>robotName</code> argument uses the full path of the robot.
<code>void deleteSnippet(String projectName, String snippetName, boolean silent)</code>	Deletes a snippet from a project. The <code>snippetName</code> argument uses the full path of the snippet.
<code>void deleteType(String projectName, String modelName, boolean silent)</code>	Deletes a type from a project. The <code>modelName</code> argument uses the full path of the type.
<code>void deployLibrary(String projectName, EmbeddedFileBasedRobotLibrary library, boolean failIfExists)</code>	Deploys a library to the server. Robots, types and resources are overridden unless <code>failIfExists</code> is true.
<code>void deployResource(String projectName, String resourceName, byte[] resourceBytes, boolean failIfExists)</code>	Deploys a resource to a project. If a resource with the given name already exists, it can be overridden by setting <code>failIfExists</code> to false. The <code>resourceName</code> argument uses the full path of the resource.
<code>void deployRobot(String projectName, String robotName, byte[] robotBytes, boolean failIfExists)</code>	Deploys a robot to a project. If a robot with the given name already exists, it can be overridden by setting <code>failIfExists</code> to false. The <code>robotName</code> argument uses the full path of the robot.
<code>void deploySnippet(String projectName, String snippetName, byte[] snippetBytes, boolean failIfExists)</code>	Deploys a snippet to a project. If a snippet with the given name already exists, it can be overridden by setting <code>failIfExists</code> to false. The <code>snippetName</code> argument uses the full path of the snippet.
<code>void deployType(String projectName, String typeName, byte[] typeBytes, boolean failIfExists)</code>	Deploys a type to a project. If a type with the given name already exists, it can be overridden by setting <code>failIfExists</code> to false. The <code>typeName</code> argument uses the full path of the type.
<code>Project[] getProjects()</code>	Returns the projects that exist in this repository.
<code>Cluster[] getRoboServerClusters()</code>	Returns a list of clusters and online(valid) RoboServers that are registered with the Management Console running the repository.
<code>Cluster[] getRoboServerClusters(boolean onlineRoboServer)</code>	Returns a list of clusters and RoboServers registered with the Management Console. Use the <code>onlineRoboServer</code> flag to indicate if the list of clusters should include only RoboServers that are online or all of the RoboServers.
<code>Cluster addRoboServer(String clusterName, int portNumber, String host)</code>	Adds a new RoboServer to a cluster.
<code>Robot[] getRobotsInProject(String projectName)</code>	Returns the full path of the Basic Engine Robots available in the project.

Method signature	Description
<code>RobotSignature getRobotSignature(String projectName, String robotName)</code>	Returns the robot signature with the full path of the robot, as well as the input variables required to execute this robot and a list of the types it may return or store.
<code>RepositoryFolder getProjectInventory(String projectName)</code>	Returns the entire tree of folders and files from the repository.
<code>RepositoryFolder getFolderInventory(String projectName, String folderPath)</code>	Returns the folders and files of the subfolder in the specified project from the repository.
<code>RepositoryFolder getFileInventory(String projectName, String folderPath, String fileName, RepositoryFile.Type fileType)</code>	Gets the file and the referenced files from the management console. Note that the file inventory is wrapped in <code>RepositoryFolder</code> to get references.
<code>void deleteFile(RepositoryFile file)</code>	Deletes the specified file from the repository.
<code>Date getCurrentDate()</code>	Returns current date and time of the Management Console.
<code>byte[] getBytes(RepositoryFile file)</code>	Returns the size in bytes of the specified file in the repository.
<code>void updateFile(RepositoryFile file, byte[] bytes)</code>	Updates the specified file in the repository with new bytes.
<code>void moveFile (RepositoryFile sourceFile, String destFolderPath)</code>	Moves the specified file from the repository to a folder specified in <code>destFolderPath</code> .
<code>void renameRobot(RepositoryFile robotFile, String newName)</code>	Renames the specified robot file.
<code>void deleteFolder(String projectName, String folderPath)</code>	Deletes the specified folder in the repository.
<code>void deleteRoboServer(String clusterName, RoboServer roboServer)</code>	Deletes a RoboServer.
<code>Map&lt;String, String&gt; getInfo()</code>	Returns information about the Management Console and the Repository API The method returns a mapping of the following: <ul style="list-style-type: none"> <li>• "application" to the version of the Management Console containing major, minor and dot version, for example, 11.5.0</li> <li>• "repository" to the ID of the latest DTD used by the Repository API, such as: <code>//Kapow Technologies//DTD Repository 1.5//EN</code></li> <li>• "rql" to the ID of the latest DTD used by the Robot Query Language API, such as: <code>//Kapow Technologies//DTD RoboSuite Robot Query Language 1.13//EN</code></li> </ul>
<code>pingRepository()</code>	Pings the repository server and returns <code>null</code> if succeeded, and an error string otherwise.

Method signature	Description
<code>deployConnector(String projectName, String connectorName, byte[] connectorBytes, boolean failIfExists, AdditionalInfo additionalInfo)</code>	Deploys a connector in the repository.
<code>deleteConnector(String projectName, String connectorName, boolean silent, AdditionalInfo additionalInfo)</code>	Deletes a connector from the repository.
<code>getRobotsByTag(String projectName, String tag)</code>	Retrieves the robots with a specified tag.

 The full path is relative to your project folder.

Proxy servers must be specified explicitly when creating the `RepositoryClient`. Standard http proxy servers without authentication are supported. NTLM proxy servers with authentication are also supported.

Check the `RepositoryClient` JavaDoc for additional details.

## Deployment with Repository Client

The following example shows how to deploy a robot and a type from the local file system using the `RepositoryClient`.

### Deployment using RepositoryClient:

```
String user = "test";
String password = "test1234";
RepositoryClient client = new RepositoryClient("http://localhost:50080", user,
    password);
try {
    FileInputStream robotStream = new FileInputStream
        ("c:\\MyRobots\\Library\\Test.robot");
    FileInputStream typeStream = new FileInputStream
        ("c:\\MyRobots\\Library\\Test.type");

    // Use the Kapow Java APIs StreamUtil to convert InputStream to byte[].
    // For production we recommend IOUtils.toByteArray(InputStream i)
    // in the commons-io library from apache.
    byte[] robotBytes = StreamUtil.readStream(robotStream).toByteArray();
    byte[] typeBytes = StreamUtil.readStream(typeStream).toByteArray();

    // we assume that no one has deleted the Default project
    client.deployRobot("Default project", "Test.robot", robotBytes, true);
    client.deployType("Default project", "Test.type", typeBytes, true);
}
catch (FileNotFoundException e) {
    System.out.println("Could not load file from disk " + e.getMessage());
}
catch (IOException e) {
    System.out.println("Could not read bytes from stream " + e.getMessage());
}
catch (FileAlreadyExistsException e) {
    // either the type or file already exist in the give project
    System.out.println(e.getMessage());
}
```

}

## Repository Rest API

The repository API is actually a group of restful services and URLs where data can be posted.

All the repository client methods that retrieve information from the repository send XML to the Repository, and the Repository responds with XML. All deploy methods post bytes to the Repository (information encoded in URL) and the Repository returns XML to acknowledge. The format of the XML sent and received is governed by a DTD found at [www.kapowtech.com](http://www.kapowtech.com).

The following is an example of all the XML-based requests. All messages must start with the following declaration:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE repository-request PUBLIC "-//Kapow Technologies//
DTD Repository 1.5//EN" "http://www.kapowtech.com/robosuite/
repository_1_5.dtd">
```

If Management Console is deployed at `http://localhost:8080/ManagementConsole`, the requests must be posted to `http://localhost:8080/ManagementConsole/secure/RepositoryAPI?format=xml`

### Snippets

A number of XML snippets are used throughout the API and the following are snippets used in the examples. We recommend studying the DTD to understand the structure of the data.

When sending requests, we often need to describe a file. Similarly, responses contain data about a file. The following table shows snippets that are found shortened in the examples. The constructs have been added to the 1.5 DTD to assist in project synchronization between Design Studio and Management Console.

Snippet Name	Code
repository-file-request	<pre>&lt;repository-file-request&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;name&gt;ExName&lt;/name&gt; &lt;type&gt;snippet&lt;/type&gt; &lt;path&gt;subfolder&lt;/path&gt; &lt;last-modified&gt;2019-02-01 19:26:12.321&lt;/last-modified&gt; &lt;last-modified-by&gt;username&lt;/last-modified-by&gt; &lt;checksum&gt;a342ddaf&lt;/checksum&gt; &lt;/repository-file-request&gt;</pre>
repository-file	<pre>&lt;repository-file&gt;&lt;name&gt;filename&lt;/name&gt; &lt;type&gt;ROBOT&lt;/name&gt;&lt;last-modified&gt;2019-02-01 19:26:12.321&lt;/last-modified&gt;&lt;last-modified-by&gt;username&lt;/last-modified-by&gt;&lt;checksum&gt;a342ddaf&lt;/checksum&gt;&lt;dependencies&gt;&lt;dependency&gt;&lt;name&gt;exsnippet&lt;/name&gt;&lt;type&gt;snippet&lt;/type&gt;&lt;/dependency&gt; &lt;/dependencies&gt;&lt;/repository-file&gt;</pre>

## REST Operations

Method	Example Request	Example Response
delete-file (robot)	<pre>&lt;repository-request&gt; &lt;delete-file file-type="robot" silent="true"&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;file-name&gt;InputA.type&lt;/file-name&gt; &lt;/delete-file&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt;&lt;delete-successful/&gt;&lt;/repository-response&gt;</pre>
delete-file (type)	<pre>&lt;repository-request&gt; &lt;delete-file file-type="type" silent="false"&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;file-name&gt;InputA.type&lt;/file-name&gt; &lt;/delete-file&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt;&lt;error type="file-not-found"&gt;Could not find a Type named InputA.type in project 'Default project'&lt;/error&gt;&lt;/repository-response&gt;</pre>
delete-file (snippet)	<pre>&lt;repository-request&gt; &lt;delete-file file-type="snippet" silent="true"&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;file-name&gt;InputA.type&lt;/file-name&gt; &lt;/delete-file&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt;&lt;delete-successful/&gt;&lt;/repository-response&gt;</pre>
delete-file (resource)	<pre>&lt;repository-request&gt; &lt;delete-file file-type="resource" silent="true"&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;file-name&gt;InputA.type&lt;/file-name&gt; &lt;/delete-file&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt;&lt;delete-successful/&gt;&lt;/repository-response&gt;</pre>
get-projects	<pre>&lt;repository-request&gt; &lt;get-projects/&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt;&lt;project-list&gt;&lt;project-name&gt;Default project&lt;/project-name&gt;&lt;/project-list&gt;&lt;/repository-response&gt;</pre>
get-robots-in-project	<pre>&lt;repository-request&gt; &lt;get-robots-in-project&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;/get-robots-in-project&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt;&lt;robot-list&gt;&lt;robot&gt;&lt;robot-name&gt;DoNothing.robot&lt;/robot-name&gt;&lt;version&gt;10.7&lt;/version&gt;&lt;last-modified&gt;2019-10-11 18:24:12.648&lt;/last-modified&gt;&lt;/robot&gt;&lt;/robot-list&gt;&lt;/repository-response&gt;</pre>
get-robot-signature	<pre>&lt;repository-request&gt; &lt;get-robot-signature&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;robot-name&gt;DoNothing.robot&lt;/robot-</pre>	<pre>&lt;repository-response&gt;&lt;robot-signature&gt;&lt;robot-name&gt;DoNothing.robot&lt;/robot-name&gt;&lt;version&gt;10.7&lt;/version&gt;&lt;last-modified&gt;2019-10-11 18:24:12.648&lt;/last-modified&gt;&lt;input-object-list&gt;&lt;input-object&gt;&lt;variab</pre>

Method	Example Request	Example Response
	<pre>name&gt; &lt;/get-robot-signature&gt; &lt;/repository-request&gt;</pre>	<pre>le-name&gt;InputA&lt;/variable-name&gt; e&gt;&lt;type-name&gt;InputA&lt;/type-name&gt; e&gt;&lt;input-attribute-list&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;aString&lt;/attribute-name&gt;&lt;attribute-type&gt;Short Text&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;anInt&lt;/attribute-name&gt;&lt;attribute-type&gt;Integer&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;aNumber&lt;/attribute-name&gt;&lt;attribute-type&gt;Number&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;aSession&lt;/attribute-name&gt;&lt;attribute-type&gt;Session&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;aBoolean&lt;/attribute-name&gt;&lt;attribute-type&gt;Boolean&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;aDate&lt;/attribute-name&gt;&lt;attribute-type&gt;Date&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;aCharacter&lt;/attribute-name&gt;&lt;attribute-type&gt;Character&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute&gt;&lt;attribute-name&gt;anImage&lt;/attribute-name&gt;&lt;attribute-type&gt;Image&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;/input-attribute-list&gt;&lt;/input-object&gt;&lt;input-object&gt;&lt;variable-name&gt;InputB&lt;/variable-name&gt;&lt;type-name&gt;InputB&lt;/type-name&gt;&lt;input-attribute-list&gt;&lt;input-attribute-required="true"&gt;&lt;attribute-name&gt;aString&lt;/attribute-name&gt;&lt;attribute-type&gt;Short Text&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute-required="true"&gt;&lt;attribute-name&gt;anInt&lt;/attribute-name&gt;&lt;attribute-type&gt;Integer&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute-required="true"&gt;&lt;attribute-name&gt;aNumber&lt;/attribute-name&gt;&lt;attribute-type&gt;Number&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute requir</pre>

Method	Example Request	Example Response
		<pre> ed="true"&gt;&lt;attribute-name&gt;aSession&lt;/attribute-name&gt;&lt;attribute-type&gt;Session&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute required="true"&gt;&lt;attribute-name&gt;aBoolean&lt;/attribute-name&gt;&lt;attribute-type&gt;Boolean&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute required="true"&gt;&lt;attribute-name&gt;aDate&lt;/attribute-name&gt;&lt;attribute-type&gt;Date&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute required="true"&gt;&lt;attribute-name&gt;aCharacter&lt;/attribute-name&gt;&lt;attribute-type&gt;Character&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;input-attribute required="true"&gt;&lt;attribute-name&gt;anImage&lt;/attribute-name&gt;&lt;attribute-type&gt;Image&lt;/attribute-type&gt;&lt;/input-attribute&gt;&lt;/input-attribute-list&gt;&lt;/input-object&gt;&lt;/input-object-list&gt;&lt;returned-type-list&gt;&lt;returned-type&gt;&lt;type-name&gt;OutputA&lt;/type-name&gt;&lt;returned-attribute-list&gt;&lt;returned-attribute&gt;&lt;attribute-name&gt;aString&lt;/attribute-name&gt;&lt;attribute-type&gt;Short Text&lt;/attribute-type&gt;&lt;/returned-attribute&gt;&lt;/returned-attribute-list&gt;&lt;/returned-type&gt;&lt;/returned-type-list&gt;&lt;stored-type-list/&gt;&lt;/robot-signature&gt;&lt;/repository-response&gt; </pre>

Method	Example Request	Example Response
get-project-inventory	<pre>&lt;repository-request&gt; &lt;get- project-inventory&gt; &lt;project- name&gt;Default project&lt;/project- name&gt; &lt;/get-project-inventory&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;repository-folder&gt; &lt;path&gt;&lt;/ path&gt; &lt;sub-folders&gt; -- repository-folders (recursively) -- &lt;/sub- folders&gt; &lt;files&gt; -- zero, one or more repository- file elements -- &lt;/files&gt; &lt;references&gt; -- zero, one or more repository-file elements needed by robots in folder -- &lt;/references&gt; &lt;/repository- folder&gt; &lt;/repository-response&gt;</pre>
get-folder-inventory	<pre>&lt;repository-request&gt; &lt;get- folder-inventory&gt; &lt;project- name&gt;Default project&lt;/project- name&gt; &lt;path&gt;subfolder&lt;/path&gt; &lt;/get-folder-inventory&gt; &lt;/ repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;repository-folder&gt; &lt;path&gt;&lt;/ path&gt; &lt;sub-folders&gt; -- repository-folders (recursively) -- &lt;/sub- folders&gt; &lt;files&gt; -- zero, one or more repository- file elements -- &lt;/files&gt; &lt;references&gt; -- zero, one or more repository-file elements needed by robots in folder -- &lt;/references&gt; &lt;/repository- folder&gt; &lt;/repository-response&gt;</pre>
get-file-inventory	<pre>&lt;repository-request&gt; &lt;get- file-inventory&gt; &lt;project- name&gt;Default project&lt;/project- name&gt; &lt;path&gt;subfolder&lt;/ path&gt; &lt;name&gt;robotname&lt;/name&gt; &lt;type&gt;robot&lt;/type&gt; &lt;/get- file-inventory&gt; &lt;/repository- request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;repository-folder&gt; &lt;path&gt;&lt;/ path&gt; &lt;sub-folders&gt; -- repository-folders (recursively) -- &lt;/sub- folders&gt; &lt;files&gt; -- zero, one or more repository- file elements -- &lt;/files&gt; &lt;references&gt; -- zero, one or more repository-file elements needed by robots in folder -- &lt;/references&gt; &lt;/repository- folder&gt; &lt;/repository-response&gt;</pre>
update-file	<pre>&lt;repository-request&gt; &lt;update- file&gt; &lt;repository-file- request&gt;...&lt;/repository-file- request&gt; &lt;file-bytes&gt;&lt;/update- file&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;update- successful/&gt; &lt;/repository- response&gt;</pre>
get-clusters	<pre>&lt;repository-request&gt; &lt;get-clusters online- roboserver='true'/&gt; &lt;/ repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;clusters&gt; &lt;cluster name='ClusterName' ssl='false'&gt; &lt;roboserver host='localhost' port='50000' primary='true'/&gt; &lt;/cluster&gt; &lt;/clusters&gt; &lt;/repository- response&gt;</pre>

Method	Example Request	Example Response
add-roboserver	<pre>&lt;repository-request&gt; &lt;add-roboserver&gt; &lt;cluster name='ClusterName' ssl='false'&gt; &lt;roboserver host='localhost' port='50000' primary='true' /&gt; &lt;/cluster&gt; &lt;roboserver host='localhost' port='50001' primary='true' /&gt; &lt;/add-roboserver&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;clusters&gt; &lt;cluster name='ClusterName' ssl='false'&gt; &lt;roboserver host='localhost' port='50000' primary='true' /&gt; &lt;roboserver host='localhost' port='50001' primary='true' /&gt; &lt;/cluster&gt; &lt;/clusters&gt; &lt;/repository-response&gt;</pre>
delete-roboserver	<pre>&lt;repository-request&gt; &lt;add-roboserver&gt; &lt;cluster name='ClusterName' ssl='false'&gt; &lt;roboserver host='localhost' port='50000' primary='true' /&gt; &lt;roboserver host='localhost' port='50001' primary='true' /&gt; &lt;/cluster&gt; &lt;roboserver host='localhost' port='50001' primary='true' /&gt; &lt;/add-roboserver&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;cluster name='ClusterName' ssl='false'&gt; &lt;roboserver host='localhost' port='50000' primary='true' /&gt; &lt;/cluster&gt; &lt;/repository-response&gt;</pre>
delete-folder	<pre>&lt;repository-request&gt; &lt;delete-folder&gt; &lt;project-name&gt;Default project&lt;/project-name&gt; &lt;path&gt;path/to/empty/folder&lt;/path&gt; &lt;/delete-folder&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;delete-successful/&gt; &lt;/repository-response&gt;</pre>
move-file	<pre>&lt;repository-request&gt; &lt;move-file&gt; &lt;repository-file-request&gt;...&lt;/repository-file-request&gt; &lt;path&gt;new/destination/path&lt;/path&gt; &lt;/move-file&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;update-successful/&gt; &lt;/repository-response&gt;</pre>
Rename-robot	<pre>&lt;repository-request&gt; &lt;rename-robot&gt; &lt;repository-file-request&gt;...&lt;/repository-file-request&gt; &lt;file-name&gt;newnameofrobot&lt;/file-name&gt; &lt;/rename-robot&gt; &lt;/repository-request&gt;</pre>	<pre>&lt;repository-response&gt; &lt;update-successful/&gt; &lt;/repository-response&gt;</pre>

**i** Robot, type, snippet, and resource names must be specified as full path. The full path is relative to your project folder.

The deployment is done by posting the raw bytes (the octet-stream is sent as a post body) to the following URLs. The following is an example where the Repository is deployed on `http://localhost:8080/ManagementConsole`.

**Methods of the deploy operations:**

Operation	URL
deploy robot	<code>http://localhost:8080/ManagementConsole/secure/RepositoryAPI?format=bytes&amp;operation=deployRobot&amp;projectName=Defaultproject&amp;fileName=DoNothing.robot&amp;failIfExists=true</code>
deploy type	<code>http://localhost:8080/ManagementConsole/secure/RepositoryAPI?format=bytes&amp;operation=deployType&amp;projectName=Defaultproject&amp;fileName=InputA.type&amp;failIfExists=true</code>
deploy Snippet	<code>http://localhost:8080/ManagementConsole/secure/RepositoryAPI?format=bytes&amp;operation=deploySnippet&amp;projectName=Defaultproject&amp;fileName=A.snippet&amp;failIfExists=true</code>
deploy resource	<code>http://localhost:8080/ManagementConsole/secure/RepositoryAPI?format=bytes&amp;operation=deployResource&amp;projectName=Defaultproject&amp;fileName=resource.txt&amp;failIfExists=true</code>
deploy library	<code>http://localhost:8080/ManagementConsole/secure/RepositoryAPI?format=bytes&amp;operation=deployLibrary&amp;projectName=Defaultproject&amp;fileName=NA&amp;failIfExists=true</code>

If authentication is enabled on Management Console, the URL `http://localhost:8080/ManagementConsole/secure/RepositoryAPI` is protected by basic authentication. This allows you to include credentials in the URL in the following way: `http://username:password@localhost:8080/ManagementConsole/secure/RepositoryAPI`.

## Management Console API

It is possible to queue execution of robots on the Management Console. Instead of running the robot directly on the RoboServer, the robot is placed in the queue on the Management Console. Be aware that some features such as setting the execute ID, defining the database connections, setting the max run time, and forcing a robot to stop on API exceptions cannot be controlled when queuing execution of robots. The following are benefits of queuing:

- Robots are queued even when resources such as devices are not available.
- Robots are routed to the correct RoboServer when multiple versions of RoboServers are installed.
- You do not need to manage clusters while building an application. The clusters are managed on the project level on the Management Console.

### Configure Java API

To configure Java API for QueuedRequests:

1. Compile the code.
2. Add the location of the .jar file to the `classpath` when running the code.
3. Create the queue.

See the detailed information and examples that follow.

## Queue a robot run

Use the `QueuedRequest` class to queue a robot run on the Management Console. For detailed information, refer to the [Kofax RPA Java API Documentation](#).

**i** Code is case-sensitive.

### JAVA API Example:

```
RepositoryHttpClientProvider repository = new RepositoryRobotLibrary("http://localhost:50080/", "Default project", 60000, "admin", "admin");
QueuedRequest request = new QueuedRequest("myfolder/myrobot.robot", "Default project", repository);
request.setPriority(QueuedRequest.Priority.HIGH);
RQLResult result = request.execute();
```

### Constructors

Constructor	Description
<code>QueuedRequest(String robotURL, String projectName, RepositoryHttpClientProvider httpClientProvider)</code>	Creates a new <code>QueuedRequest</code> with for the specified robot. Valid entries are comprised of three required parameters specifying the robot URL, project name, and repository. Properties extend the request. See the following table for Properties parameters.
<code>QueuedRequest(String robotURL, String projectName, RepositoryHttpClientProvider httpClientProvider, Priority priority, long timeout)</code>	Creates a new <code>QueuedRequest</code> with the specified robot URL, priority, and timeout time.

### Properties

Property	Description
<code>getPollingIntervalMillis() / setPollingIntervalMillis(int pollingIntervalMillis)</code>	Updates to the robot run status. Returns values and API exception errors by polling. This function gets the interval in milliseconds between polls. Short intervals cause more load on the Management Console but increase the rate of updates per request. The default value is 1000 (1 second).
<code>getRobotURL() / setRobotURL(String robotName)</code>	The name of the robot to run, including a path if the robot resides in a folder.  <b>i</b> The URL part of the property is not an actual URL. The name was chosen for reasons of backward compatibility.

Property	Description
<code>getPriority() / setPriority(Priority priority)</code>	The priority of the request in the queue: MINIMUM, LOW, MEDIUM, HIGH, or MAXIMUM. The default value is MEDIUM.
<code>setStopRobotOnApiException(boolean stopOnError)</code>	When set, the robot is stopped on the RoboServer after the first API exception is sent to the client. The default value is <code>true</code> .
<code>getTimeout() / setTimeout(long timeout)</code>	The maximum time in seconds that the robot waits in the queue for a RoboServer to run the robot. The default value is 600 (10 minutes).

## Methods

Method	Description
<code>createInputVariable(String name)</code>	Creates a new Input Object with the specified name, and returns an RQLObjectBuilder that you can use to build the object.
<code>createInputVariable(String name, RQLObject rqlObject)</code>	Creates a new Input Object with the specified name from <code>rqlObject</code> . This object is useful if responses from one robot are used as input to another robot.
<code>createOAuthInputVariable(String name, String userName, String applicationName)</code>	Creates an input variable for an OAUTH input type that looks up the OAuth details on the Management Console, based on the user name and application name. Ensure that on the Management Console the application and OAuth user are linked to the same project as the robot you are requesting to run.
<code>execute()</code>	Places the robot in the queue for running, then waits for it to terminate.
<code>execute(RobotResponseHandler handler)</code>	Places the robot in the queue for running, then calls the handler at various points during the request.

## Chapter 2

# .NET Programmer's Guide

This chapter describes how to execute robots using the Kofax RPA legacy .NET API. The guide assumes that you know how to write simple robots, and that you are familiar with the C# programming language.

You can find information about specific .NET classes in the compiled help, `robosuite-dotnet-api.chm`, located in your offline documentation folder. For more details, see the *Kofax RPA Installation Guide*.

## .NET Basics

Using the .NET API, any .NET-based application can become a client to an RPA instance. The .NET API targets .NET Standard 2.0, building applications on either .NET (Core) 2.0 to 6.0, or .NET Framework 4.7.2 and higher.

In addition to running robots that store data in a database, you can also have the robots return data directly back to the client application. Here are some examples:

- Use multiple robots to do a search that aggregates results from multiple sources in real time.
- Run a robot in response to an event on your application back end. For example, run a robot when a new user signs up to create accounts on web-based systems not integrated directly into your back end.

This guide introduces the core classes, and how to use them for executing robots. It also describes how to provide input to robots and control their execution on a RoboServer.

The .NET API is a .dll file that is located in `API/legacy/robosuite-dotnet-api/lib/robosuite-dotnet-api.dll` inside the Kofax RPA installation folder (see the "Important Folders in Kofax RPA" topic in the *Installation Guide* for details). All examples in this guide can be found in `API/legacy/robosuite-dotnet-api/examples`. The `Newtonsoft.Json.dll` is a required third-party library located with the .NET API file.

## First Example

The following is the code required to execute the robot named `NewsMagazine.robot`, which is located in the Tutorials folder of the default project. The robot outputs its results using the Return Value step action, which makes it easy to handle the output programmatically using the API. Other robots (typically those run in a schedule by the Management Console) store their data directly in a database using the Store in Database step action, in which case data collected by the robot is not returned to the API client.

In the following example, the NewsMagazine robot is executed and the output is processed programmatically.

### Execute a Robot without input:

```
using System;
using System.Collections.Generic;
using System.Text;
using Com.KapowTech.RoboSuite.Api;
using Com.KapowTech.RoboSuite.Api.Repository.Construct;
using Com.KapowTech.RoboSuite.Api.Construct;

namespace Examples
{
    class Program
    {
        static void Main(string[] args)
        {
            var server = new RoboServer("localhost", 50000);
            var ssl = false;
            var cluster = new Cluster("MyCluster", new RoboServer[]{ server}, ssl);

            Request.RegisterCluster(cluster); // you can only register a cluster
            once per application

            var request = new Request("Library:/Tutorials/NewsMagazine.robot");
            request.RobotLibrary = new DefaultRobotLibrary();
            RqlResult result = request.Execute("MyCluster");

            foreach (RqlObject value in result.GetOutputObjectsByName("Post")) {
                var title = value["title"];
                var preview = value["preview"];
                Console.WriteLine(title + ", " + preview);
            }
            Console.ReadKey();
        }
    }
}
```

The following table lists the classes involved and their responsibilities.

RoboServer	This is a simple value object that identifies a RoboServer that can execute robots. Each RoboServer must be activated by a Management Console and assigned KCU before use.
Cluster	A cluster is a group of RoboServers functioning as a single logical unit.
Request	This class is used to construct the robot request. Before you can execute any requests, you must register a cluster with the Request class.
DefaultRobotLibrary	A robot library instructs RoboServer where to find the robot identified in the request. Later examples explore the various robot library types and when/how to use them.
RQLResult	This contains the result of a robot execution. The result contains value responses, log, and server messages.
RQLObject	Each value that is returned from a robot using the Return Value action can be accessed as an RQLObject.

The first line tells the API that our RoboServer is running on localhost port 50000.

```
var server = new RoboServer("localhost", 50000);
```

The following lines define a cluster with a single RoboServer. The cluster is registered with the Request class, allowing you to execute request on this cluster. Each cluster can only be registered once per application, which is done during the initialization of the application.

### Registering a cluster:

```
var ssl = false;
var cluster = new Cluster("MyCluster", new RoboServer[] { server }, ssl);
Request.RegisterCluster(cluster);
```

The followed code creates a request that executes the robot named `NewsMagazine.robot` located at `Library:/Tutorials`. `Library:/` refers to the robot Library configured for the request. Here the `DefaultRobotLibrary` is used, which instructs the RoboServer to look for the robot in the servers local file system. See [Robot Libraries](#) for details on how to use robot libraries.

```
var request = new Request("Library:/Tutorials/NewsMagazine.robot");
request.RobotLibrary = new DefaultRobotLibrary();
```

The next line executes the robot on the cluster named `MyCluster` (the cluster registered previously) and returns the result once the robot is done. If an error occurs while the robot is executing, an exception is thrown here.

```
RqlResult result = request.Execute("MyCluster");
```

Finally we process the extracted values. First, we get all extracted values of the type named `Post` and iterate through them. For each `RqlObject`, we access the attributes of the `Post` type and print the result. Attributes and mappings are discussed in a later section.

```
foreach (RqlObject value in result.GetOutputObjectsByName("Post")) {
    var title = value["title"];
    var preview = value["preview"];
    Console.WriteLine(title + ", " + preview);
}
```

## Robot Input

Most robots executed through the API are parametrized through input, such as a search keyword, or login credentials. Input to a robot is part of the request to RoboServer and is provided using the `createInputVariable` method on the request.

### Input using implicit RqlObjectBuilder

```
var request = new Request("Library:/Tutorials/Input.robot");
request.CreateInputVariable("userLogin").SetAttributeEntry
("username", "scott").SetAttributeEntry("password", "tiger");
```

In the preceding code, we create a Request and use `CreateInputVariable` to create an input variable named `userLogin`. We then use `setAttribute` to configure the user name and password attributes of the input variable.

The preceding example is a common shorthand notation, but can also be expressed in more detail by using the `RqlObjectBuilder`:

```
var request = new Request("Library:/NewsMagazine.robot");
RqlObjectBuilder userLogin = request.CreateInputVariable("userLogin");
userLogin.SetAttributeEntry("username", "scott");
userLogin.SetAttributeEntry("password", "tiger");
```

The two examples are identical. The first utilizes the cascading method invocation on the anonymous `RqlObjectBuilder` and is therefore shorter.

When RoboServer receives this request the following occurs:

- RoboServer loads `Input.robot` (from a `RobotLibrary` configured for the request).
- RoboServer verifies that the robot has a variable named `userLogin` and that this variable is marked as input.
- RoboServer now verifies that the attributes that we configured using `setAttribute` are compatible with the type of variable `userLogin`. As a result the type must have attributes named user name and password and that they must both be text-based attributes (the next section describes the mapping between API and Design Studio attributes).
- If all input variables are compatible, RoboServer starts executing the robot.

If a robot requires multiple input variables, you must create all of them to execute the robot. You only have to configure required attributes; any no-required attributes that you do not configure through the API will just have a null value. If you have a robot that requires login to both Facebook and Twitter, you could define the input as follows.

```
Request request = new Request("Library:/Input.robot");
request.CreateInputVariable("facebook").SetAttributeEntry
("username", "scott").SetAttributeEntry("password", "facebook123");
request.CreateInputVariable("twitter").SetAttributeEntry
("username", "scott").SetAttributeEntry("password", "twitter123");
```

## Attribute Types

When you define a new type in Design Studio, you select an attribute type for each attribute. Some attributes can contain text such as Short Text, Long Text, Password, HTML, XML, and when used inside a robot, there may be requirements to the text stored in these attributes. If you store text in an XML attribute, the text must be a valid XML document. This validation occurs when the type is used inside a robot, but as the API does not know anything about the type, it does not validate attribute values in the same manner. As a result, the API only has eight attribute types and Design Studio has 19 available types. This table shows the mapping between the API and Design Studio attribute types.

### API to Design Studio mapping

API Attribute Type	RoboServer Attribute Type
Text	Short Text, Long Text, Password, HTML, XML, Properties, Language, Country, Currency, Refind Key
Integer	Integer
Boolean	Boolean
Number	Number
Character	Character
Date	Date
Session	Session
Binary	Binary, Image, PDF

The API attribute types are then mapped to .NET in the following way.

## .Net Types for Attributes

API Attribute Type	Java Class
Text	System.String (string)
Integer	System.Int64
Boolean	System.Boolean (bool)
Number	System.Double (double)
Character	System.Char (char)
Date	System.DateTime
Session	Com.Kapowtech.Robosuite.Api.Construct.Session
Binary	Com.Kapowtech.Robosuite.Api.Construct.Binary

The `RqlObjectBuilder` `setAttribute` method is overloaded so you do not need to specify the attribute type explicitly when configuring an attribute through the API, as long as the right .NET class is used as an argument. Here is an example that shows how to set the attributes for an object with all possible Design Studio attribute types.

Recommended usage of `setAttribute`:

```
RqlObjectBuilder inputBuilder = request.CreateInputVariable("AllTypes");
inputBuilder.SetAttributeEntry("anInt", 42L);
inputBuilder.SetAttributeEntry("aNumber", 12.34d);
inputBuilder.SetAttributeEntry("aBoolean", true);
inputBuilder.SetAttributeEntry("aCharacter", 'c');
inputBuilder.SetAttributeEntry("aShortText", "some text");
inputBuilder.SetAttributeEntry("aLongText", "a longer text");
inputBuilder.SetAttributeEntry("aPassword", "secret");
inputBuilder.SetAttributeEntry("aHTML", "<html>text</html>");
inputBuilder.SetAttributeEntry("anXML", "<tag>text</tag>");
inputBuilder.SetAttributeEntry("aDate", DateTime.Now);
inputBuilder.SetAttributeEntry("aBinary", (Binary) null);
inputBuilder.SetAttributeEntry("aPDF", (Binary) null);
inputBuilder.SetAttributeEntry("anImage", (Binary) null);
inputBuilder.SetAttributeEntry("aProperties", "name=value\nname2=value2");
inputBuilder.SetAttributeEntry("aSession", (Session) null);
inputBuilder.SetAttributeEntry("aCurrency", "USD");
inputBuilder.SetAttributeEntry("aCountry", "US");
inputBuilder.SetAttributeEntry("aLanguage", "en");
inputBuilder.SetAttributeEntry("aRefindKey", "Never use as input");
```

In the preceding example, we have to cast null values because the C# compiler cannot otherwise determine which of the overloaded version of `SetAttributeEntry` method to call. However, as unconfigured attributes are automatically null, you never need to set null explicitly.

It is possible to specify the `Attribute` and `AttributeType` explicitly when creating input using the API. This approach is not recommended, but may be needed in rare cases, and would look similar to the following.

Not recommended usage of `setAttribute`

```
RqlObjectBuilder inputBuilder = request.CreateInputVariable("alltypes");
inputBuilder.SetAttributeEntry(new AttributeEntry("anInt", "42",
AttributeEntryType.Integer));
inputBuilder.SetAttributeEntry(new AttributeEntry("aNumber", "12.34",
```

```

    AttributeEntryType.Number));
inputBuilder.SetAttributeEntry(new AttributeEntry("aBoolean", "true",
    AttributeEntryType.Boolean));
inputBuilder.SetAttributeEntry(new AttributeEntry("aCharacter", "c",
    AttributeEntryType.Character));
inputBuilder.SetAttributeEntry(new AttributeEntry("aShortText", "some text",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aLongText", "a longer text",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aPassword", "secret",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aHTML", "<html>text</html>",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("anXML", "<tag>text</tag>",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aDate",
    "2012-01-15 23:59:59.123", AttributeEntryType.Date));

inputBuilder.SetAttributeEntry(new AttributeEntry("aBinary", null,
    AttributeEntryType.Binary));
inputBuilder.SetAttributeEntry(new AttributeEntry("aPDF", null,
    AttributeEntryType.Binary));
inputBuilder.SetAttributeEntry(new AttributeEntry("anImage", null,
    AttributeEntryType.Binary));
inputBuilder.SetAttributeEntry(new AttributeEntry("aProperties",
    "name=value\nname2=value2", AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aCurrency", "USD",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aCountry", "US",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aLanguage", "en",
    AttributeEntryType.Text));
inputBuilder.SetAttributeEntry(new AttributeEntry("aRefindKey",
    "Never use this as input", AttributeEntryType.Text));

```

All attribute values must be provided in the form of strings. The string values are then converted to the appropriate .NET objects based on the `AttributeEntryType` provided. It is only useful if you build other generic APIs on top of the Kofax RPA .NET API.

## Execution Parameters

In addition to the `CreateInputVariable` method, the Request contains a number of properties that controls how the robot executes on a RoboServer.

### Execution Control Methods on Request

ApiKey	Authorizes access to resources such as RFS, DTS, and the password store. If omitted, the credentials provided on the connection are used.
MaxExecutionTime	Controls the execution time of the robot in seconds. When this time is elapsed, the robot is stopped by RoboServer. The timer does not start until the robot begins to execute, so if the robot is queued on RoboServer, this is not taken into account.

<code>StopOnConnectionLost</code>	When true (default), the robot stops if RoboServer discovers that the connection to the client application is lost. If you set this value to false and your code is not written to handle this, your application may not perform as expected.
<code>StopRobotOnApiException</code>	When true (default), the robot is stopped by RoboServer after the first API exception is raised. By default, most steps in a robot raise an API exception if the step fails to execute. Configure this value on the Error Handling tab for the step.  When set to false, the robot continues to execute regardless of API exceptions. However, unless your application is using the <code>IRobotResponseHandler</code> for streaming the results, an exception is still thrown by <code>Execute()</code> . Be cautious when setting it to false.
<code>Username, Password</code>	Sets the RoboServer credentials. RoboServer can be configured to require authentication. When this option is enabled, the client must provide credentials or RoboServer rejects the request.
<code>RobotLibrary</code>	Assigns a <code>RobotLibrary</code> to the request. A robot library instructs RoboServer where to find the robot identified in the request. For more examples related to the various library types and their usage, see <a href="#">Robot Libraries</a> .
<code>ExecutionId</code>	Allows you to set the <code>executionId</code> for this request. If you do not provide it, RoboServer generates it automatically. The execution ID is used for logging and also needed to stop the robot programmatically. The ID must be globally unique (over time). If two robots use the same execution ID, the logs will be inconsistent.  Setting this property is useful if your robots are part of a larger workflow and you already have a unique identifier in your client application, because it allows you to join the robot logs with the rest of the system.
<code>setProject(String)</code>	This method is used solely for logging purposes. Management Console uses this field to link log messages to project, so the log views can filter by project.  If your application is not using the <code>RepositoryRobotLibrary</code> , you may set this value to inform the RoboServer logging system which project (if any) this robot belongs to.

## Robot Libraries

In Design Studio, robots are grouped into projects. If you look in the file system, you will see that these projects are represented by a folder with the only constraint that it must contain a folder named `Library`.

When you build the execute request for RoboServer, you identify the robot by a robot URL:

```
Request request = new Request("Library:/Input.robot");
```

Here, `Library:/` is a symbolic reference to a robot library, in which the RoboServer should look for the robot. The `RobotLibrary` is then specified on the builder in the following way:

```
request.setRobotLibrary(new DefaultRobotLibrary());
```

Three different robot library implementations are available. The one to select depends on your deployment environment.

## Robot Libraries

Library Type	Description
DefaultRobotLibrary	<p>This library configures RoboServer to look for the robot in the current project folder. This folder is defined in the Settings application.</p> <p>If you have multiple RoboServers, you must deploy your robots on all RoboServers.</p> <p>This robot library is not cached, so the robot is reloaded from disk with every execution. This approach makes the library usable in a development environment where robots change often, but not suitable for a production environment.</p>
EmbeddedFileBasedRobotLibrary	<p>This library is embedded in the execute request sent to RoboServer. To create this library, you need to create a .zip file containing the robots and all its dependencies (types, snippets and resources). This can be done the <b>Tools &gt; Create Robot Library File</b> menu in Design Studio.</p> <p>The library is sent with every request, which adds some overhead for large libraries, but the libraries are cached on RoboServer, which offers best possible performance.</p> <p>One strength is that robots and code can be deployed as a single unit, which offers clean migration from QA environment to production environment. However, if the robots change often, you have to redeploy them often.</p> <p>You can use the following code to configure the embedded robot library for your request.</p> <pre>var request = new Request ("Library:/Tutorials/NewsMagazine. robot"); var stream = new FileStream ("c:\\embeddedLibrary.robotlib",  FileMode.Open); request.RobotLibrary = new EmbeddedFileBasedRobotLibrary (stream);</pre>

Library Type	Description
RepositoryRobotLibrary	<p>This is the most flexible <code>RobotLibrary</code>.</p> <p>This library uses the built-in repository of Management Console as a robot library. When you use this library, <code>RoboServer</code> contacts the Management Console that sends a robot library containing the robot and its dependencies.</p> <p>Caching occurs on a per robot basis, inside both Management Console and <code>RoboServer</code>. Inside Management Console, the generated library is cached based on the robot and its dependencies. On <code>RoboServer</code>, the cache is based on a timeout, so it does not have to ask the Management Console for each request. In addition, the library loading between <code>RoboServer</code> and Management Console uses HTTP public/private caching, to further reduce bandwidth.</p> <p>If <code>NewsMagazine.robot</code> is uploaded to the Management Console, you can use the repository robot library when executing the robot:</p> <pre data-bbox="857 892 1464 1071">var request = new Request   ("Library:/Tutorials/NewsMagazine.   robot"); request.RobotLibrary =   new RepositoryRobotLibrary   ("http://localhost:50080",   "Default Project", 60000);</pre> <p>This command instructs <code>RoboServer</code> to load the robot from a local Management Console and caches it for one minute before checking with the Management Console to see if a new version of the robot (its type and snippets) is available.</p> <p>In addition, any resource loaded through the <code>Library:/ protocol</code> will cause <code>RoboServer</code> request the resource directly from the Management Console.</p>

## .NET Advanced

This section describes advanced API features, including output streaming, logging and SSL configuration, as well as parallel execution.

### Load Distribution

Inside the `RequestExecutor`, the executor is given an array of `RoboServers`. As the executor is constructed, it tries to connect to each `RoboServer`. Once connected, it sends a ping request to each `RoboServer` to discover how the server is configured.

#### Load balanced executor

```
RoboServer prod = new RoboServer("prod.kapow.local", 50000);
RoboServer prod2 = new RoboServer("prod2.kapow.local", 50000);
Cluster cluster = new Cluster("Prod", new RoboServer[] { prod, prod2}, false);
```

```
Request.RegisterCluster(cluster);
```

Load is distributed to each online RoboServer in the cluster based on the number of unused execution slots on the RoboServer. The next request is always distributed to the RoboServer with the most available slots. The number of available execution slots is obtained through the initial ping response, and the executor keeps track of each robot it starts, and when it is completed. The number of execution slots on a RoboServer is determined by the **Max concurrent robots** setting in the Management Console > Admin > RoboServers section.

If a RoboServer goes offline, it does not receive any robot execution requests before it successfully responded to the ping request.

## One Client Rule

By default, API connections are limited to 20 connections. However, to ensure the best performance, we recommend that you have only one API client using a given cluster of RoboServers. If you have too many JVMs running robots against the same RoboServers, it will result in reduced performance.

Although the following is not recommended, if your environment requires the handling of a higher volume, you can configure the connection limit by adjusting the `kapow.max.multiplexing.clients` system property in the `common.conf` file.

## Data Streaming

If you need to present the results from a robot execution in real-time, you can use the API to return the extracted values immediately instead of waiting for the robot to finish its execution and access the `RqlResult`.

The API offers the possibility to receive a callback every time the API receives a value that was returned by the robot. Do this through the `IRobotResponseHandler` interface.

### Response streaming using `AbstractFailFastRobotResponseHandler`

```
using System;
using Com.KapowTech.RoboSuite.Api;
using Com.KapowTech.RoboSuite.Api.Repository.Construct;
using Com.KapowTech.RoboSuite.Api.Construct;
using System.IO;
using Com.KapowTech.RoboSuite.Api.Engine.Hotstandby;

namespace Examples
{
    public class DataStreaming {
        public static void Main(String[] args) {
            var server = new RoboServer("localhost", 50000);
            var cluster = new Cluster("MyCluster", new RoboServer[] { server },
                false);
            Request.RegisterCluster(cluster);

            var request = new Request("Library:/Tutorials/NewsMagazine.robot");
            IRobotResponseHandler handler = new SampleResponseHandler();
            request.Execute("MyCluster", handler);
        }
    }
}
```

```

    }

    public class SampleResponseHandler : AbstractFailFastRobotResponseHandler
    {
        override public void HandleReturnedValue (RobotOutputObjectResponse
            response, IStoppable stoppable)
        {
            var title = response.OutputObject["title"];
            var preview = response.OutputObject["preview"];
            Console.WriteLine(title + ", " + preview);
        }
    }
}

```

The preceding example uses the second execute method of the Request, which expects a `RobotResponseHandler` in addition to the name of the cluster to execute the robot on. In this example, create a `IRobotResponseHandler` by extending `AbstractFailFastRobotResponseHandler`, which provides default error handling, to handle the values returned by the robot.

The `handleReturnedValue` method is called whenever the API receives a returned value from `RoboServer`. The `AbstractFailFastRobotResponseHandler` used in this example throws exceptions in the same way as the non-streaming execute method. This means that an exception is thrown in response to any API exceptions generated by the robot.

The `IRobotResponseHandler` has several methods which can be grouped into three categories.

### Robot life cycle events

Methods called when the robot execution state change on `RoboServer`, such as when it starts and finishes its execution.

### Robot data events

Methods which are called when the robot returns data or errors to the API.

### Additional error handling

Methods which are called either due to an error inside `RoboServer` or in the API.

### RobotResponseHandler - robot life cycle events

Method name	Description
<code>void requestSent (RoboServer roboServer, ExecuteRequest request)</code>	Called when the <code>RequestExecutor</code> finds the server that executes the request.
<code>void requestAccepted (String executionId)</code>	Called when the found <code>RoboServer</code> accepts the request and puts it into a queue.
<code>void RobotStarted (IStoppable stoppable)</code>	Called when the <code>RoboServer</code> begins to execute the robot. This usually occurs immediately after the robot is queued, unless the <code>RoboServer</code> is under heavy load, or used by multiple API clients.

Method name	Description
<code>void robotDone(RobotDoneEvent reason)</code>	Called when the robot is done executing on RoboServer. The <code>RobotDoneEvent</code> is used to specify if the execution terminated normally, due to an error, or if it was stopped.

### RobotResponseHandler - robot data events

Method name	Description
<code>void HandleReturnedValue(RobotOutputObjectResponse response, IStoppable stoppable)</code>	Called when the robot is executed a Return Value action and the value has been returned via the socket to the API.
<code>void HandleRobotError(RobotErrorResponse response, IStoppable stoppable)</code>	Called when the robot raises an API exception. Under normal circumstances the robot stops executing after the first API exception. This behavior can be overridden by using <code>Request.StopRobotOnApiException = false</code> , in which case this method is called multiple times. This is useful if you need a data streaming robot to continue to execute regardless of any generated errors.
<code>void HandleWriteLog(RobotMessageResponse response, IStoppable stoppable)</code>	Called if the robot executes the Write Log action. This is useful to provide additional logging info from a robot.

### RobotResponseHandler - additional error handling

Method name	Description
<code>void HandleServerError(ServerErrorResponse response, IStoppable stoppable)</code>	Called if RoboServer generates an error. For example, if the server is too busy to process any requests, or if an error occurs inside RoboServer, which prevents it from starting the robot.
<code>void handleError(RQLEException e, IStoppable stoppable)</code>	Called if an error occurs inside the API. Most commonly if the client loses the connection to RoboServer.

Many of the methods include a `IStoppable` object, which can be used to stop after a specific error occurred or a value was returned.

Some of these methods give you the ability to throw an `RQLEException`. The thread that calls the handler is the thread that calls `Request.Execute()`, which means that any exceptions thrown can overload the call stack. If you throw an exception in response to `handleReturnedValue`, `handleRobotError` or `handleWriteLog`, it is your responsibility to invoke `Stoppable.stop()`, or the robot may continue to execute even though the call to `Request.Execute()` is completed.

Data streaming is most often used in one of the following use cases.

- Ajax based web application, where results are presented to the user in real-time. If data is not streamed, results cannot be shown until the robot is done running.

- Robots that return so much data that the client would not be able to hold it all in memory throughout the robot execution.
- Processes that need to be optimized so the extracted values are processed in parallel with the robot execution.
- Processes that store data in databases in a custom format.
- Robots that should ignore or require custom handling of API exceptions (see the following example).

### Response and error collecting using `AbstractFailFastRobotResponseHandler`:

```
using System;
using System.Collections;
using System.Collections.Generic;
using Com.KapowTech.RoboSuite.Api;
using Com.KapowTech.RoboSuite.Api.Repository.Construct;
using Com.KapowTech.RoboSuite.Api.Construct;
using System.IO;
using Com.KapowTech.RoboSuite.Api.Engine.Hotstandby.Interfaces;

namespace Examples
{
    public class DataStreaming
    {
        public static void Main(String[] args)
        {
            var server = new RoboServer("localhost", 50000);
            var cluster = new Cluster("MyCluster", new RoboServer[] { server },
                false);
            Request.RegisterCluster(cluster);

            var request = new Request("Library:/Tutorials/NewsMagazine.robot");
            request.StopRobotOnApiException = false; // IMPORTANT!!

            ErrorCollectingRobotResponseHandler handler =
                new ErrorCollectingRobotResponseHandler();
            request.Execute("MyCluster", handler); // blocks until robot is
                done, or handler throws an exception

            Console.WriteLine("Extracted values:");
            foreach (RobotOutputObjectResponse response in handler.
                GetOutput())
            {
                var title = response.OutputObject["title"];
                var preview = response.OutputObject["preview"];
                Console.WriteLine(title + ", " + preview);
            }

            Console.WriteLine("Errors:");
            foreach (RobotErrorResponse error in handler.GetErrors())
            {
                Console.WriteLine(error.ErrorLocationCode + ", " + error.
                    ErrorMessage);
            }
        }
    }

    public class ErrorCollectingRobotResponseHandler :
        AbstractFailFastRobotResponseHandler {

```

```
private IList<RobotErrorResponse> _errors =
    new List<RobotErrorResponse>();
private IList<RobotOutputObjectResponse> _output =
    new List<RobotOutputObjectResponse>();

override public void HandleReturnedValue(RobotOutputObjectResponse
response, IStoppable stoppable) {
    _output.Add(response);
}

override public void HandleRobotError(RobotErrorResponse response,
IStoppable stoppable) {
    // do not call super as this will stop the robot
    _errors.Add(response);
}

public IList<RobotErrorResponse> GetErrors() {
    return _errors;
}

public IList<RobotOutputObjectResponse> GetOutput() {
    return _output;
}
}
```

The preceding example shows how to use a `IRobotResponseHandler` that collects returned values and errors. This type of handler is useful if the robot should continue to execute even when error are encountered, which can be useful if the website is unstable and occasionally times out. Notice that only robot errors (API exceptions) are collected by the handler. If the connection to RoboServer is lost, `Request.Execute()` still throws an `RQLException`, and the robot is stopped by RoboServer.

For more details, see the `IRobotResponseHandler` documentation.

## SSL

The API communicates with RoboServer through an `RQLService`, which is a RoboServer component that listens for API requests on a specific network port. When you start a RoboServer, you specify if it should use the encrypted SSL service, or the plain socket service, or both (using two different ports). All RoboServers in a cluster must be running the same `RQLService` (although the port may be different).

Assuming a RoboServer is started with the SSL `RQLService` on port 50043:

```
RoboServer -service ssl:50043
```

The following code can be used.

```
RoboServer server = new RoboServer("localhost", 50043);
boolean ssl = true;
Cluster cluster = new Cluster("MyCluster", new RoboServer[] {server}, ssl);
Request.RegisterCluster(cluster);
```

You need to create the cluster as an SSL cluster and specify the SSL port used by each RoboServer. Now all communication between RoboServer and the API will be encrypted.

In addition to data encryption, SSL offers the possibility to verify the identity of the remote party. This type of verification is very important on the Internet. Most often your API client and RoboServers are on the same local network, so you rarely need to verify the identity of the other party, but the API supports this feature should it become necessary.

See [Examples](#) to find out how to compile and run the included SSL example.

## Repository Integration

In Management Console, you also specify clusters of RoboServers, which are used to execute scheduled robots, as well as robots executed as REST services. The API enables you to use the `RepositoryClient` to obtain cluster information from Management Console. For more details, see the `RepositoryClient` documentation.

### Repository Integration

```
using System;
using Com.KapowTech.RoboSuite.Api;
using Com.KapowTech.RoboSuite.Api.Construct;
using Com.KapowTech.RoboSuite.Api.Repository.Engine;

namespace Examples
{
    public class RepositoryIntegration
    {
        public static void Main(String[] args)
        {
            string userName = "admin";
            string password = "admin";
            RepositoryClient client = new RepositoryClient
                ("http://localhost:50080", userName, password);

            Request.RegisterCluster(client, "Production");
            var request = new Request("Library:/Tutorials/NewsMagazine.robot");
            var result = request.Execute("Production");
            Console.WriteLine(result.ToString());
        }
    }
}
```

The preceding example shows how to create a `RepositoryClient` that connects to a Management Console deployed on localhost port 50080.

When we register the `RepositoryClient`, we specify the name of a cluster that exists on the Management Console. It then queries the Management Console to get a list of RoboServers configured for this cluster, and check every two minutes to see if the cluster configuration is updated on the Management Console.

This integration allows you to create a cluster on Management Console that you can change dynamically using the Management Console user interface. When you use a Management Console cluster with the API, usage should be exclusive, and you should not use it for scheduling robots, as this would break the One Client rule.

## Executor Logger

When you execute a request, the `execute` method throws an exception if a robot generates an error. Other types of errors and warnings are reported through the `ExecutorLogger` interface. In the previous examples, `ExecutionLogger` was not provided when executing robots, which is the default implementation that writes to `System.out`.

The following is an example of how the `ExecutorLogger` reports if one of `RoboServers` goes offline. This example configures a cluster with a `RoboServer` that is not online.

### ExecutorLogger, offline server example:

```
RoboServer rs = new RoboServer("localhost", 50000);
Cluster cluster = new Cluster("name", new RoboServer[]{rs}, false);
Request.RegisterCluster(cluster);
```

If you run this example, it writes the following to the console.

### ExecutorLogger, offline RoboServer console output:

```
RoboServer[Host=localhost, Port=50000]' went offline.
Com.KapowTech.RoboSuite.Api.Engine.UnableToConnectException:.....
```

If you do not need your application to write directly to `System.out`, you can provide a different `IExecutorLogger` implementation when registering the cluster:

### Use DebugExecutorLogger:

```
Request.RegisterCluster(cluster, new DebugExecutorLogger());
```

This example uses the `DebugExecutorLogger()` that also writes to `System.out`, but only if the API debugging is enabled. Alternatively, you can provide your own implementation of the `ExecutorLogger` to control how error messages should be handled.

## Under the Hood

This section explains what is happening under the hood when you register a cluster and execute requests.

When you register a cluster with the request, a `RequestExecutor` is created behind the scene. This `RequestExecutor` is stored in a `Map` using the cluster name as key. When a request is executed, the provided cluster name is used to find the associated `RequestExecutor` and execute the request.

### Normal execution

```
public static void Main(String[] args)
{
    RoboServer server = new RoboServer("localhost", 50000);
    Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, false);
    Request.RegisterCluster(cluster);

    var request = new Request("Library:/Tutorials/NewsMagazine.robot");
    request.RobotLibrary = new DefaultRobotLibrary();
    var result = request.Execute("MyCluster");
}
```

```
    Console.WriteLine(result);  
}
```

Now write the same example using the `hiddenRequestExecutor` directly.

Under the hood execution:

```
public static void Main(String[] args)  
{  
    RoboServer server = new RoboServer("localhost", 50000);  
    Cluster cluster = new Cluster("MyCluster", new RoboServer[]{ server}, false);  
    RequestExecutor executor = new RequestExecutor(cluster);  
  
    var request = new Request("Library:/Tutorials/NewsMagazine.robot");  
    request.RobotLibrary = new DefaultRobotLibrary();  
    var result = executor.Execute(request);  
    Console.WriteLine(result);  
}
```

The `RequestExecutor` is hidden by default, so you do not have to keep track of it. You may only create one `RequestExecutor` per cluster, so if you use it directly, you need to store a reference to it throughout your application. Using `Request.RegisterCluster(cluster)` means that you can ignore the `RequestExecutor` and lifecycle rules.

The `RequestExecutor` contains the necessary state and logic, which provides the load balancing and failover features. Using the `RequestExecutor` directly also offers a few extra features.

## RequestExecutor Features

When the `RequestExecutor` is not connected to a repository, you can dynamically add or remove `RoboServers` by calling `AddRoboServer(..)` and `RemoveRoboServer(..)`. These methods modify the distribution list used inside the `RequestExecutor`.

The `RequestExecutor.TotalAvailableSlots` property contains the number of unused execution slots across all `RoboServers` in the internal distribution list.

By using these methods, you can dynamically add `RoboServers` to your `RequestExecutor` once the number of available execution slots becomes low.

When you create the `RequestExecutor`, you may optionally provide an `IRqlEngineFactory`. The `IRqlEngineFactory` allows you to customize which `RQLProtocol` is used when connecting to a `RoboServer`. This is needed only under rare circumstances, such as to use a client certificate to increase security. See the *Certificates* chapter in the *Kofax RPA Administrator's Guide* for details.

## Repository API

The Repository API allows you to query the repository of Management Console to get a list of projects, robots, and the input required to call a robot. It also enables you to programmatically deploy robots, types, and resource files.

## Repository Client

Communication with the repository is achieved through the `RepositoryClient` in the namespace `Com.KapowTech.RoboSuite.Api.Repository.Engine`.

### Get Projects from Repository

```
string UserName = "admin";
string Password = "admin1234";
RepositoryClient client = new RepositoryClient("http://localhost:50080/", UserName,
    Password);
Project[] projects = client.GetProjects();
foreach(Project p in projects) {
    Console.WriteLine(p);
}
```

Here, a `RepositoryClient` is configured to connect to the repository of Management Console on `http://localhost:50080/`, with a user name and password.

After the `RepositoryClient` is created, the `GetProjects()` method is used to query the repository for a list of projects. Notice that when calling any of the `RepositoryClient` methods, a `RepositoryClientException` is thrown if an error occurs.

The `RepositoryClient` has the following methods.

### Methods of the RepositoryClient

Method signature	Description
<code>string ComputeChecksum(byte[] bytes)</code>	Returns the checksum of the specified file to verify data integrity.
<code>void DeleteConnector(string projectName, string connectorName, bool silent, AdditionalInfo additionalInfo)</code>	Deletes a connector from a project. The <code>connectorName</code> argument specifies the full path of the connector.
<code>void DeleteFile(RepositoryFile file, AdditionalInfo additionalInfo)</code>	Deletes the specified file from the repository.
<code>void DeleteFolder(string projectName, string folderPath, AdditionalInfo additionalInfo)</code>	Deletes the specified folder from the repository.
<code>void DeleteResource(string projectName, string resourceName, bool silent, AdditionalInfo additionalInfo)</code>	Deletes the specified resource from the repository.
<code>void DeleteRobot(string projectName, string robotName, bool silent, AdditionalInfo additionalInfo)</code>	Deletes the specified robot from the repository.
<code>void DeleteSnippet(string projectName, string snippetName, boolean silent, AdditionalInfo additionalInfo)</code>	Deletes the specified snippet from the repository.
<code>void DeleteType(string projectName, string typeName, bool silent, AdditionalInfo additionalInfo)</code>	Deletes the specified type from the repository.

Method signature	Description
void <b>DeployConnector</b> (string projectName, string connectorName, byte[] connectorBytes, bool failIfExists, AdditionalInfo additionalInfo)	Deploys a connector to a project. If a connector with the given name already exists, it can be overwritten by setting <code>failIfExists</code> to false.
void <b>DeployLibrary</b> (string projectName, EmbeddedFileBasedRobotLibrary library, bool failIfExists, AdditionalInfo additionalInfo)	Deploys a library to the server. If robots, types and resources with the given names already exist, they can be overwritten by setting <code>failIfExists</code> to false.
void <b>DeployResource</b> (string projectName, string resourceName, byte[] resourceBytes, bool failIfExists, AdditionalInfo additionalInfo)	Deploys a resource to a project. If a resource with the given name already exists, it can be overwritten by setting <code>failIfExists</code> to false.
void <b>DeployRobot</b> (string projectName, string robotName, byte[] robotBytes, bool failIfExists, AdditionalInfo additionalInfo)	Deploys a robot to a project. If a robot with the given name already exists, it can be overwritten by setting <code>failIfExists</code> to false.
void <b>DeploySnippet</b> (string projectName, string snippetName, byte[] snippetBytes, bool failIfExists, AdditionalInfo additionalInfo)	Deploys a snippet to a project. If a snippet with the given name already exists, it can be overwritten by setting <code>failIfExists</code> to false.
void <b>DeployType</b> (string projectName, string typeName, byte[] typeBytes, boolean failIfExists, AdditionalInfo additionalInfo)	Deploys a type to a project. If a type with the given name already exists, it can be overwritten by setting <code>failIfExists</code> to false.
byte[] <b>GetBytes</b> (RepositoryFile file)	Returns the contents of the specified file.
DateTime <b>GetCurrentDate</b> ()	Returns the current date and time of the Management Console.
RepositoryFolder <b>GetFileInventory</b> (string projectName, string folderName, string fileName, FileType fileType)	Returns the file and the referenced files from the project. Note that the file inventory is wrapped in a <code>RepositoryFolder</code> to get references.
RepositoryFolder <b>GetFolderInventory</b> (string projectName, string folderName)	Returns the folders and files of the subfolder in the project.
IDictionary<string, string> <b>GetInfo</b> ()	Returns information about the Management Console and the Repository API. The method returns a mapping with: <ul style="list-style-type: none"> <li>"application": The version of the Management Console containing major, minor, and dot version, for example: 11.5.0</li> <li>"repository": The ID of the latest DTD used by the Repository API, such as <code>//Kapow Technologies//DTD Repository 1.6//EN</code></li> <li>"rql" to the ID of the latest DTD used by the Robot Query Language API, such as <code>//Kapow Technologies//DTD RoboSuite Robot Query Language 1.3//EN</code></li> </ul>

Method signature	Description
RepositoryFolder <b>GetProjectInventory</b> (string projectName)	Returns the entire tree of folders and files from the repository.
Project[] <b>GetProjects</b> ()	Returns the projects that exist in this repository.
Cluster[] <b>GetRoboServerClusters</b> (bool onlineRoboServers)	Returns a list of clusters and RoboServers that are registered with the Management Console. The <code>onlineRoboServer</code> flag indicates if only RoboServers that are online should be included.
Robot[] <b>GetRobotsByTag</b> (string projectName, string tagFragment)	Returns a list of robots with the tag containing the <code>tagFragment</code> from the project.
RobotSignature <b>GetRobotSignature</b> (string projectName, string robotName)	Returns the robot signature with the full path of the robot, as well as the input variables required to execute this robot, and a list of the types it may return or store.
Robot[] <b>GetRobotsInProject</b> (string projectName)	Returns the robots available in the project.
void <b>MoveFile</b> (RepositoryFile file, string destinationPath)	Moves the specified file in the repository to the folder specified in <code>destinationPath</code> .
string <b>PingRepository</b> ()	Pings the repository server. Returns null if the server works fine. Returns an error message in case of incorrect behavior.
<b>RemoteCertificateValidationCallback</b>	Contains the current proxy server configuration.
void <b>RenameRobot</b> (RepositoryFile robotFile, string newName)	Renames the specified robot file.
<b>ServerCertificateValidationCallback</b>	Contains the current callback used to validate server certificates.
void <b>UpdateFile</b> (RepositoryFile file, byte[] bytes, AdditionalInfo additionalInfo)	Overwrites the specified file in the repository with new content.

 The full path is relative to your project folder.

`AdditionalInfo` parameter contains comments that appear in the Commit message column on the Resources page of the Management Console. This parameter is optional.

The request may be declined if the credentials given do not have sufficient access.

The repository is accessed via http. When using the .Net version of the Repository API, any proxy servers configured for the system will be used by the Repository API.

## Deployment with Repository Client

The following example shows how to deploy a robot and a type from the local file system using the `RepositoryClient`.

### Deploying to Repository

```
string user = "test";
string password = "test1234";
RepositoryClient client = new RepositoryClient("http://localhost:50080", user,
    password);

byte[] robotBytes = File.ReadAllBytes("c:\\MyRobots\\Library\\Test.robot");
byte[] typeBytes = File.ReadAllBytes("c:\\MyRobots\\Library\\Test.type");

// we assume that no one has deleted the Default project
client.deployRobot("Default project", "Test.robot", robotBytes, true);
client.deployType("Default project", "Test.type", typeBytes, true);
```

## Repository API as Rest

The repository can also be accessed via [restful services](#).

## Logging

Primarily for troubleshooting, the .NET API provides logging data. It does not write the logging data, instead a plugin is provided so the application can integrate .NET API logging with the application's own logging. The application registers a callback, or interface, to log data. In this way, the application integrates API data logging.

The logging functionality resides in the `Com.KapowTech.RoboSuite.Api.Logging` namespace.

- To access the simplest form of logging, register a delegate function `public delegate void Logger(Level level, string msg);` with `SimpleLogger.SetLogger(Logger logger)`. The delegate is called when the API has something to log, passing the log level and message. The delegate is not called if the maximum error level is exceeded.
- To set the error level, use the `SimpleLogger.LogLevel` property, with values `Fatal`, `Error`, `Warn`, `Info`, and `Debug`.

If the functionality of the `SimpleLogger` does not provide what you want, register an implementation of the `ILogFactory` interface with `Registered.Logger` in the application. This interface should return objects implementing the `ILog` interfaces for specific types (components of the API) upon request. For more information refer to the compiled help.

Applications that use `log4net` for logging can use the `log4netlogging.dll` assembly found in the `API/lib/log4netlogging` directory.

The `Logging` class in the `Com.KapowTech.RoboSuite.Api.Log4NetLogging` namespace provides two methods to register `log4net` logging:

- `Logging.Install(string config_file)` initiates `log4net` logging, configured from the configuration file.
- `Install()` requires the application to configure `log4net` itself.

If no logging method is registered, the API silently ignores all logging data.

## Management Console API

It is possible to queue execution of robots on the Management Console. Instead of running the robot directly on the RoboServer, the robot is placed in the queue on the Management Console. Be aware that some features such as setting the execute ID, defining the database connections, setting the max run time, and forcing a robot to stop on API exceptions cannot be controlled when queuing execution of robots. The following are benefits of queuing:

- Robots are queued even when resources such as devices are not available.
- Robots are routed to the correct RoboServer when multiple versions of RoboServers are installed.
- You do not need to manage clusters while building an application. The clusters are managed on the project level on the Management Console.

### Queue a robot run

Use the `QueuedRequest` class to queue a robot run on the Management Console.

 Code is case-sensitive.

#### NET API Example:

```
QueuedRequest request = new QueuedRequest("myfolder/myrobot.robot");
request.RobotLibrary = new RepositoryRobotLibrary
    ("http://localhost:50080/", "Default Project",
    60000, "admin", "admin");
request.Priority = QueuedRequestPriority.HIGH;
SqlResult result = request.Execute();
```

#### Constructors

Constructor	Description
<code>QueuedRequest(String robot)</code>	Creates a new <code>QueuedRequest</code> with the specified robot. Properties extend the request. See the following table for Properties parameters.

#### Properties

Property	Description
<code>PollingIntervalMillis</code>	Updates to the robot run status. Returns values and API exception errors by intervals in milliseconds between polls. Short intervals cause more load on the Management Console but increase the rate of updates per request. The default value is 1000 (1 second).

Property	Description
RobotURL	<p>The name of the robot to run, including a path if the robot resides in a folder.</p> <p> The URL part of the property is not an actual URL. The name was chosen for reasons of backward compatibility.</p>
RobotLibrary	The robot library to use in the request. You must set a robot library before calling <code>execute()</code> .
Priority	<p>The priority of the request in the queue: <code>MINIMUM</code>, <code>LOW</code>, <code>MEDIUM</code>, <code>HIGH</code>, or <code>MAXIMUM</code>.</p> <p>The default value is <code>MEDIUM</code>.</p>
StopRobotOnApiException	<p>When set, the robot is stopped on the RoboServer after the first API exception is sent to the client.</p> <p>The default value is <code>true</code>.</p>
Timeout	<p>The maximum time in seconds that the robot waits in the queue for a RoboServer to run the robot.</p> <p>The default value is <code>600</code> (10 minutes).</p>

## Methods

Method	Description
<code>CreateInputVariable(String name)</code>	Creates a new Input Object with the specified name, and returns an <code>RQLObjectBuilder</code> that you can use to build the object.
<code>CreateInputVariable(String name, RQLObject rqlObject)</code>	Creates a new Input Object with the specified name from <code>rqlObject</code> . This object is useful if responses from one robot are used as input to another robot.
<code>CreateRQLObjectBuilder(String name)</code>	Creates a new <code>RQLObjectBuilder</code> that creates an <code>RQLObject</code> with the given name.
<code>CreateOAuthInputVariable(String name, String userName, String applicationName)</code>	Creates an input variable for an OAUTH input type that looks up the OAuth details on the Management Console, based on the user name and application name. Ensure that on the Management Console the application and OAuth user are linked to the same project as the robot you are requesting to run.
<code>Execute()</code>	Places the robot in the queue for running, then waits for it to terminate.
<code>Execute(RobotResponseHandler handler)</code>	Places the robot in the queue for running, then calls the handler at various points during the request.

## Chapter 3

# Management Console REST API

This chapter provides information on the Management Console REST services provided with the product. The REST services can be accessed from the Swagger UI using the following example URL:

<http://localhost:8080/ManagementConsole/api/swagger-ui.html>

The following REST services are available in Kofax RPA 11.5.0.

REST service	Purpose
<a href="#">tasks</a>	Queuing of robot tasks. With this service, you can get an example structure of robot input required to run the robot, queue robot tasks, and obtain robot execution result.

## Tasks

This is the REST service for robot task queuing.

### Methods

#### POST `robotInputExample`

Used for getting an example structure of the robot input values required to run the robot. These are the values that you configure in the "Configure input" step during schedule creation.

In the **Parameters** section, edit the request body to specify the `projectName` and `robotName` properties and then click **Execute**. The response will contain the example structure of your robot input that you can use to create a request to queue robot tasks.

#### POST `queueRobot`

Used for queuing of robot tasks.

In the **Parameters** section, edit the request body as shown here:

1. In the `priority` property, specify the most suitable priority level: `MINIMUM`, `LOW`, `MEDIUM`, `HIGH`, or `MAXIMUM`. Tasks that have a higher priority are provided access to the required resources and are executed sooner than those having a lower priority. See "Queuing of Schedule Jobs" in *Kofax RPA Help* for more information.
2. Specify the `projectName` and `robotName` properties.
3. In the `robotInputConfig` property, paste the input example structure that you obtained with the `robotInputExample` method and edit the input values as appropriate.
4. In the `timeout` property, specify the timeout when the tasks are to stop queuing.

5. Click **Execute**.

**GET getRobotOutput/{ticket}**

Used for getting the result of robot execution, such as robot output, queuing status, and error information.

When the POST queueRobot request is executed, a unique execution ticket is generated for this request. Copy the ticket from the queueRobot response and paste it in the **Parameters** section in the getRobotOutput request. Click **Execute**.

The response will contain the status and result of the robot execution. If the robot contains any output, it is written into the `values` property.
